ADVERTISEMENT

TO

THE FOURTH VOLUME.

It was stated in a former Advertisement,* that the second part of Mr STEWART's Dissertation on the History of *Metaphysical, Ethical, and Political Philosophy*, would accompany the present Half-Volume. Circumstances having rendered it necessary to postpone the appearance of that Part, till a later period in the progress of this Work, it was agreed, that the remaining Part of PROFESSOR PLAYFAIR's Dissertation on the History of the *Mathematical and Physical Sciences* should, in the mean time, take its place. It is to this arrangement, that the World is indebted for a Piece, which, though it only forms part of a greater design, cannot but be regarded as a most valuable contribution to the History of Science; whilst it derives a melancholy interest, from its being the last literary object that employed the talents, and engaged the solicitude, of its eminent author.

Mr PLAYFAIR's Dissertation was intended to furnish an historical sketch of the principal discoveries and improvements in science, from the revival of Letters to the beginning of the present century; and, in that portion of it which is prefixed to the *Second* Volume of this work, the history is brought down to the period marked by the commencement of Newton's discoveries. The remaining half was to have completed the design, in *three* parts or subdivisions; the First comprehending the period of NEWTON and LEIBNITZ;

---

* *Advertisement* to Volume Third.

the second, that of EULER and D'ALEMBERT; and the Third, that of LAGRANGE and LAPLACE.

Mr PLAYFAIR was proceeding, with his accustomed diligence and ardour, in the execution of this interesting and congenial task, when he was seized with the illness of which he died. The *first* subdivision of his plan, which embraces a view of the advances made in the most remarkable period of the history of Science, was happily completed, and the printing finished, while he was yet able to correct the Press. It is now given to the Public, under the painful impression that it must too probably be considered as a *Fragment;* for the Editor fears, that the materials collected for the completion of the Dissertation, though containing the results of much elaborate inquiry, and profound reflection, cannot be put into a shape that would justify their publication as a work of PROFESSOR PLAYFAIR.

Edinburgh, *December* 1819.

DISSERTATION SECOND.

SKETCH OF THE PROGRESS OF NATURAL PHILOSOPHY FROM THE REVIVAL OF LEARNING TO THE PRESENT TIME.

PART SECOND.

FROM THE COMMENCEMENT OF NEWTON'S DISCOVERIES TO THE YEAR 1818.

In the former part of this sketch, the history of each division of the sciences was continued without interruption, from the beginning to the end. During the period, however, on which I am now to enter, the advancement of knowledge has been so rapid, and marked by such distinct steps, that several pauses or resting-places occur, of which it may be advisable to take advantage. Were the history of any particular science to be continued for the whole of the busy interval which this second part embraces, it would leave the other sciences too far behind; and would make it difficult to perceive the mutual action by which they have so much assisted the progress of one another. Considering some sort of subdivision, therefore, as necessary, and observing, in the interval which extends from the first of Newton's discoveries to the year 1818, three different conditions of the Physico-Mathematical sciences, well marked and distinguished by great improvements, I have divided the above interval into three corresponding parts. The first of these, reaching from the commencement of Newton's discoveries in 1663, to a little beyond his death, or to 1730, may be denominated, from the men who impressed on it its peculiar character, *the period of Newton and Leibnitz*. The second, which, for a similar reason, I call that of *Euler and D'Alembert*, may be regarded as extending from 1730 to 1780; and the third, that of *Lagrange and Laplace*, from 1780 to 1818.

PERIOD FIRST.

SECTION I.

THE NEW GEOMETRY.

THE seventeenth century, which had advanced with such spirit and success in combating prejudice, detecting error, and establishing truth, was destined to conclude with the most splendid series of philosophical discoveries yet recorded in the history of letters. It was about to witness, in succession, the invention of Fluxions, the discovery of the Composition of Light, and of the principle of Universal Gravitation,—all three within a period of little more than twenty years, and all three the work of the same individual. It is to the first of these that our attention at present is to be particularly directed.

The notion of Infinite Quantity had, as we have already seen, been for some time introduced into Geometry, and having become a subject of reasoning and calculation, had, in many instances, after facilitating the process of both, led to conclusions from which, as if by magic, the idea of infinity had entirely disappeared, and left the geometer or the algebraist in possession of valuable propositions, in which were involved no magnitudes but such as could be readily exhibited. The discovery of such results had increased both the interest and extent of mathematical investigation.

It was in this state of the sciences, that Newton began his mathematical studies, and, after a very short interval, his mathematical discoveries.[1] The book, next to the elements, which was put into his hands, was Wallis's *Arithmetic of Infinites*, a work well fitted for suggesting new views in geometry, and calling into activity the powers of mathematical invention. Wallis had effected the quadrature of all those curves in which the value of one of the co-ordinates can be expressed in terms of the other, without involving either fractional or negative exponents. Beyond this point neither his researches, nor those of any other geometer, had yet reached, and from this point the discoveries of Newton began. The Savilian Professor had himself been extremely desirous to advance into the new region, where, among other great objects, the quadrature of the circle must necessarily be contained, and he made a very noble effort to pass the barrier by which the undiscovered country appeared to be defended. He saw plainly, that if the equations of the curves which he had squared were ranged in a regular series, from the simpler to the more complex, their areas would constitute another corresponding series, the terms of which were all known. He farther remarked, that, in the first of these series, the equation to the circle itself might be introduced, and would occupy the middle place between the first and second terms of the series, or between an equation to a straight line and an equation to the common parabola. He concluded, therefore, that if, in the second series, he could interpolate a term in the middle, between its first and second terms, this term must necessarily be no other than the area of the circle. But when he proceeded to pursue this very refined and philosophical idea, he was not so fortunate; and his attempt toward the requisite interpolation, though it did not entirely fail, and made known a curious property of the area of the circle, did not lead to an indefinite quadrature of that curve.[1] Newton was much more judicious and successful in his attempt. Proceeding on the same general principle with Wallis, as he himself tells us, the simple view which he took of the areas already computed, and of the terms of which each consisted, enabled him to discover the law which was common to them all, and under which the expression for the area of the circle, as well as of innumerable other curves, must needs be comprehended. In the case of the circle, as in all those where a fractional exponent appeared, the area was exhibited in the form of an infinite series.

---

[1] He entered at Trinity College, Cambridge, in June 1660. The date of his first discoveries is about 1663.

The problem of the quadrature of the circle, and of so many other curves, being thus resolved, Newton immediately remarked, that the law of these series was, with a small alteration, the law for the series of terms which expresses the root of any binomial quantity whatsoever. Thus he was put in possession of another valuable discovery, the Binomial Theorem, and at the same time perceived that this last was in reality, in the order of things, placed before the other, and afforded a much easier access to such quadratures than the method of interpolation, which, though the first road, appeared now neither to be the easiest nor the most direct.

---

[1] The interpolation of Wallis failed, because he did not employ literal or general exponents. His theorem, expressing the area of the entire circle by a fraction, of which the numerator and denominator are each the continued product of a certain series of numbers, is a remarkable anticipation of some of Euler's discoveries, *Calc. Int.* Tom. I. cap. 8.

It is but rarely that we can lay hold with certainty of the thread by which genius has been guided in its first discoveries. Here we are proceeding on the authority of the author himself, for in a letter to Oldenburgh,[1] Secretary of the Royal Society of London, he has entered into considerable detail on this subject, adding (so ready are the steps of invention to be forgotten), that the facts would have entirely escaped his memory, if he had not been reminded of them by some notes which he had made at the time, and which he had accidentally fallen on. The whole of the letter just referred to is one of the most valuable documents to be found in the history of invention.

In all this, however, nothing occurs from which it can be inferred that the method of fluxions had yet occurred to the inventor. His discovery consisted in the method of reducing the value of y, the ordinate of a curve, into an infinite series of the integer powers of x the abscissa, by division, or the extraction of roots, that is, by the Binomial Theorem; after which, the part of the area belonging to each term could be assigned by the arithmetic of infinites, or other methods already known. He has assured us himself, however, that the great principle of the new geometry was known to him, and applied to investigation as early as 1665 or 1666.[2] Independently of that authority, we also know, on the testimony of Barrow, that soon after the period just mentioned, there was put into his hands by Newton a manuscript treatise,[3] the same which was afterwards published under the title of *Analysis per Æquationes Numero Terminorum Infinitas*, in which, though the instrument of investigation is nothing else than infinite series, the principle of fluxions, if not fully explained, is at least distinctly pointed out. Barrow strongly exhorted his young friend to publish this treasure to the world; but the modesty of the author, of which the excess, if not culpable, was certainly in the present instance very unfortunate, prevented his compliance. All this was previous to the year 1669; the treatise itself was not published till 1711, more than forty years after it was written.

For a long time, therefore, the discoveries of Newton were only known to his friends, and the first work in which he communicated any thing to the world on the subject of fluxions was in the first edition of the *Principia*, in 1687, in the second *Lemma* of the second book, to which, in the disputes that have since arisen about the invention of the new analysis, reference has been so often made. The principle of the fluxionary calculus was there pointed out, but nothing appeared that indicated the peculiar algorithm, or the new notation, which is so essential to that calculus. About this Newton had yet given no information; and it was only from the second volume of Wallis's Works, in 1693, that it became known to the world.[1] It was no less than ten years after this, in 1704, that Newton himself first published a work on the new calculus, his *Quadrature of Curves,* more than twenty-eight years after it was written.

[2] *Quadrature of Curves*, Introduction.

[3] *Com. Epist.* No. I. II. III. &c

These discoveries, however, even before the press was employed as their vehicle, could not remain altogether unknown in a country where the mathematical sciences were cultivated with zeal and diligence. Barrow, to whom they were first made known by the author himself, communicated them to Oldenburgh, the secretary of the Royal Society, who had a very extensive correspondence all over Europe. By him the series for the quadrature of the circle were made known to James Gregory,[2] in Scotland, who had occupied himself very much with the same subject. They were also communicated to Leibnitz in Germany, who had become acquainted with Oldenburgh in a visit which he made to England in 1673. At the time of that visit, Leibnitz was but little conversant with the mathematics; but having afterwards devoted his great talents to the study of that science, he was soon in a condition to make new discoveries. He invented a method of squaring the circle, by transforming it into another curve of an equal area, but having the ordinate expressed by a rational fraction of the absciss, so that its area could be found by the methods already known. In this way he discovered the series, so remarkable for its simplicity, which gives the value of a circular arch in terms of the tangent. This series he communicated to Oldenburgh in 1674, and received from him in return an account of the progress made by Newton and Gregory in the invention of series. In 1676,

---

[1] Wallis says, that he had inserted in the English edition of his book, published in 1685, several extracts from Newton's *Letters,* "*Omissis multis aliis inibi notatu dignis, eo quod speraverim clarissimum virum voluisse tum illa, tum alia quæ apud ipsum premit edidisse. Cum vero illud nondum fecerit libet eorum nonnulla hic attingere ne pereant.*" Among these last is an account of the fluxionary notation, according to which the fluxions of flowing quantities are distinguished by points, and also of certain applications of this new algorithm, extracted from two letters of Newton, written in 1792.—*Opera,* Tom. II. p. 390, &c. —There is no evidence of his notation having existed earlier than that date, though it be highly probable that it did.

[2] Note A, at the end.

Newton described his method of quadratures at the request of Oldenburgh, in order that it might be transmitted to Leibnitz in the two letters already mentioned, as of such value by recording the views which guided that great geometer in his earliest, and some of his most important discoveries. The method of fluxions is not communicated in these letters; nor are the principles of it in any way suggested; though there are, in the last letter, two sentences in transposed characters, which ascertain that Newton was then in possession of that method, and employed in speaking of it the same language in which it was afterwards made known. In the following year, Leibnitz, in a letter to Oldenburgh, introduces differentials, and the methods of his calculus for the first time. This letter,[1] which is very important, clearly proves that the author was then in full possession of the principles of his calculus; and had even invented the algorithm and notation.

From these facts, and they are all that bear directly on the question concerning the invention of the infinitesimal analysis, if they be fairly and dispassionately examined, I think that no doubt can remain, that Newton was the first inventor of that analysis, which he called by the name of Fluxions; but that, in the communications made by him, or his friends, to Leibnitz, there was nothing that could convey any idea of the principle on which that analysis was founded, or of the algorithm which it involved. The things stated were merely results; and though some of those relating to the tangents of curves might show the author to be in possession of a method of investigation different from infinite series, yet they afforded no indication of the nature of that method, or the principles on which it proceeded.

In what manner Newton's communications in the two letters already referred to, may have acted in stimulating the curiosity and extending or even directing the views of such a man as Leibnitz, I shall not presume to decide (nor even, if such effect be admitted, will it take from the originality of his discoveries); but that in the authenticated communications which took place between these philosophers, there was nothing which could make known the nature of the fluxionary calculus, I consider as a fact most fully established.

Of the new or infinitesimal analysis, we are, therefore, to consider Newton as the first inventor, Leibnitz as the second; his discovery, though posterior in time, having been made independently of the other, and having no less claim to originality. It had the advantage also of being first made known to the world; an account of it, and of its peculiar algorithm, having been inserted in the first volume of the *Acta Eruditorum*, in 1684. Thus, while Newton's discovery remained a secret, communicated only to a few friends, the geometry of Leibnitz was spreading with great rapidity over the Continent. Two most able coadjutors, the brothers James and John Bernoulli, joined their talents to those of the original inventor, and illustrated the new methods by the solution of a great variety of difficult and interesting problems. The reserve of Newton still kept his countrymen ignorant of his geometrical discoveries, and the first book that appeared in England on the new geometry was that of Craig, who professedly derived his knowledge from the writings of Leibnitz and his friends. Nothing, however, like rivalship or hostility between these inventors had yet appeared; each seemed willing to admit the originality of the other's discoveries; and Newton, in the passage of the *Principia* just referred to, gave a highly favourable opinion on the subject of the discoveries of Leibnitz.

---

[1] *Commercium Epistolicum,* No. 66.

The quiet, however, that now prevailed between the English and German philosophers, was clearly of a nature to be easily disturbed. With the English was conviction, and, as we have seen, a well grounded conviction, that the first discovery of the Infinitesimal Analysis was the property of Newton; but the analysis thus discovered was yet unknown to the public, and was in the hands of the inventor and his friends. With the Germans, there was the conviction, also well founded, that the invention of their countryman was perfectly original; and they had the satisfaction to see his calculus everywhere adopted, and himself considered all over the Continent as the sole inventor. The friends of Newton could not but resist this latter claim, and the friends of Leibnitz, seeing that their master had become the great teacher of the new calculus, could not easily bring themselves to acknowledge that he was not the first discoverer. The tranquillity that existed under such circumstances, if once disturbed, was not likely to be speedily restored.

Accordingly, a remark of Fatio de Duillier, a mathematician, not otherwise very remarkable, was sufficient to light up a flame which a whole century has been hardly sufficient to extinguish. In a paper on the line of swiftest descent, which he presented to the Royal Society in 1699, was this sentence: "I hold Newton to have been the first inventor of this calculus, and the earliest, by several years, induced by the evidence of facts; and whether Leibnitz, the second inventor, has borrowed any thing from the other, I leave to the judgment of those who have seen the letters and manuscripts of Newton." Leibnitz replied to this charge in the Leipsic *Journal*, without any asperity, simply stating himself to have been, as well as Newton, the inventor; neither contesting nor acknowledging Newton's claim to priority, but asserting his own to the first publication of the calculus.

Not long after this, the publication of Newton's *Quadrature of Curves*, and his *Enumeration of the lines of the third order* (1705), afforded the same journalists an opportunity of showing their determination to retort the insinuations of Duillier, and to carry the war into the country of the enemy. After giving a very imperfect synopsis of the first of these books, they add: " *Pro differentiis igitur Leibnitianis D. Newtonus adhibet, semperque adhibuit fluxiones; quæ sunt proxime ut fluentium augmenta equalibus temporis particulis quam minimis genita; iisque tum in suis Principiis Naturæ Mathematicis, tum in aliis post editis, eleganter est usus; quamadmodum Honoratus Fabrius in sua Synopsi Geometricâ motuum progressus Cavalierianæ methodo substituit.*"[1]

In spite of the politeness and ambiguity[2] of this passage, the most obvious meaning appeared to be, that Newton had been led to the notion of fluxions by the differentials of Leibnitz, just as Honoratus Fabri had been led to substitute the idea of progressive motion for the indivisibles of Cavalieri. A charge so entirely unfounded, so inconsistent with acknowledged facts, and so little consonant to declarations that had formerly come from the same quarter, could not but call forth the indignation of Newton and his friends, especially as it was known, that these journalists spoke the language of Leibnitz and Bernoulli. In that indignation they were perfectly justified; but when the minds of contending parties have become irritated in a certain degree, it often happens that the injustice of one side is retaliated by an equal injustice from the opposite. Accordingly, Keill, who, with more zeal than judgment, undertook the defence of Newton's claims, instead of endeavouring to establish the priority of his discoveries, by an appeal to facts and to dates that could be accurately ascertained (in which he would have been completely successful), undertook to prove, that the communications of Newton to Leibnitz, were sufficient to put the latter in possession of the principles of the new analysis, after which he had only to substitute the notion of differentials for that of fluxions. In support of a charge which it would have required the clearest and most irresistible evidence to justify, he had, however, nothing to offer but equivocal facts and overstrained arguments, such as could only convince those who were already disposed to believe. They were, accordingly, received as sound reasoning in England, rejected as absurd in Germany, and read with no effect by the mathematicians of France and Italy.

---

[1] *Com. Epist.* No. 97. Newtoni *Opera*, Tom. IV. p. 577.

[2] Note B, at the end.

Leibnitz complained of Keill's proceeding to the Royal Society of London, which declined giving judgment, but appointed a commission of its members to draw up a full and detailed report of all the communications which had passed between Newton and Leibnitz, or their friends, on subjects connected with the new analysis, from the time of Collins and Oldenburgh to the date of Keill's letter to Sir Hans Sloane in 1711, the same that was now complained of. This report forms what is called the *Commercium Epistolicum*; it was published by order of the Royal Society the year following, and contains an account of the facts, which, though in the main fair and just, does not give that impression of the impartiality of the reporters which the circumstances so imperiously demanded. Leibnitz complained of this publication; and alleged, that though nothing might be inserted that was not contained in the original letters, yet certain passages were suppressed which were favourable to his pretensions. He threatened an answer, which, however, never appeared. Some notes were added to the *Commercium*, which contain a good deal of asperity and unsupported insinuation; the *Recensio*, or review of it, inserted in the *Philosophical Transactions* for 1715, though written with ability, is still more liable to the same censure.

In the year (1713) which followed the publication of the *Commercium Epistolicum*, a paragraph was circulated among the mathematicians of Europe, purporting to be the *judgment of a mathematician* on the invention of the new analysis. The author was not named, but was generally understood to be John Bernoulli, of which, indeed, the terms in which Leibnitz speaks of the judgment leaves no room to doubt. Bernoulli was without question well acquainted with the subject in dispute; he was a perfect master of the calculus; he had been one of the great instruments of its advancement, and, except impartiality, possessed every requisite for a judge. Without offence it might be said, that he could scarcely be accounted impartial. He had been a party in all that had happened;—warmly attached as he was to the one side, and greatly exasperated against the other, his temper had been more frequently ruffled, and his passions or prejudices more violently excited, than those of any other individual. With all his abilities, therefore, he was not likely to prove the fairest and most candid judge, in a cause that might almost be considered as his own. His sentence, however, is pronounced in calm and temperate language, and amounts to this, *That there is no reason to believe, that the fluxionary calculus was invented before the differential.*

I shall refer to a note[1] the discussion of the evidence which he points out as the ground of this decision, though the facts already stated might be considered as sufficient to enable the reader to form an opinion on the subject. The friends of Leibnitz hurt their own cause, by attempting to fix on Newton a charge of plagiarism, which was refuted by such a chain of evidence, by so many dates distinctly ascertained, and so many concessions of their own. A candid review of the evidence led to the conviction, that both Newton and Leibnitz were original inventors. When the English mathematicians accused Leibnitz of borrowing from Newton, they were, therefore, going much farther than the evidence authorised them, and were mistaking their own partialities for proofs. They maintained what was not true, but what, nevertheless, was not physically impossible, the discovery of Newton being certainly prior to that of Leibnitz. The German mathematicians, on the other hand, when they charged Newton with borrowing from Leibnitz, were maintaining what was not only false, but what involved an impossibility. This is the only part of the dispute, in which any thing that could be construed into *mala fides* can be said to have appeared. I am far, however, from giving it that construction; men of such high character, both for integrity and talents, as Leibnitz and Bernoulli, ought not to be lightly subjected to so cruel an imputation. Partiality, prejudice, and passion, are sufficient to account for much injustice, without a decided intention to do wrong.

In the state of hostility to which matters were now brought, the new analysis itself was had recourse to, as affording to either side abundant means of annoying its adversaries, by an inexhaustible supply of problems, accessible to those alone who were initiated in the doctrines, and who could command the resources of that analysis. The power of resolving such problems, therefore, seemed a test whether this analysis was understood or not. Already some questions of this kind had been proposed in the Leipsic *Journal,* not as defiances, but as exercises in the new geometry. Such was the problem of the *Catenaria,* or the curve, which a chain of uniform weight makes when suspended from two points. This had been proposed by Bernoulli in 1690; and had been resolved by Huygens, Leibnitz, and himself.

A question had been proposed, also, concerning the line of swiftest descent in 1697, or the line along which a body must descend, in order to go from one point to another not perpendicularly under it, in the least time possible. Though a straight line be the shortest distance between two points, it does not necessarily follow, that the descent in that line will be most speedily performed, for, by falling in a curve that has at first a very rapid declivity, the body may acquire in the beginning of its motion so great a velocity, as shall carry it over a long line in less time than it would describe a short one, with a velocity more slowly acquired. This, however, is a problem that belongs to a class of questions of peculiar difficulty; and accordingly it was resolved only by a few of the most distinguished mathematicians. The solutions which appeared within the time prescribed were from Leibnitz, Newton, the two Bernoullis, and M. de l'Hopital. Newton's appeared in the *Philosophical Transactions* without a name; but the author was easily recognised. John Bernoulli, on seeing it, is said to have exclaimed, *Ex ungue leonem!*

---

[1] Note C, at the end.

The curve that has the property required is the cycloid; Newton has given the construction, but has not accompanied it with the analysis. He added afterwards the demonstration of a very curious theorem for determining the time of the actual descent. Leibnitz resolved the problem the same day that he received the *programme* in which it was proposed.

The problem of orthogonal trajectories, as it is called, had been long ago proposed in the *Acta Eruditorum*, with an invitation to all who were skilled in the new analysis to attempt the solution. The problem had not, at first, met with the attention it was supposed to deserve, but John Bernoulli having resumed the consideration of it, found out what appeared a very perfect and very general solution; and the question was then (1716) proposed anew by Leibnitz, for the avowed purpose of trying the skill of the English mathematicians. The question is, a system of curves described according to a known law being given (all the hyperbolas, for instance, that are described between the same assymptotes; or all the parabolas that have the same directrix, and that pass through the same point, &c.), to describe a curve which shall cut them all at right angles. This may be considered as the first defiance professedly aimed at the English mathematicians. The problem was delivered to Newton on his return from the Mint, when he was much fatigued with the business of the day; he resolved it, however, the same evening, and his solution, though without a name, is given in the *Philosophical Transactions* for 1716.[1]

This solution, however, only gave rise to new quarrels, for hardly any thing so excellent could come from the one side, that it could meet with the entire approbation of the other. Newton's indeed, was rather the plan or *projet* of an investigation, than an actual solution; and, in the general view which it took of the question, could hardly provide against all the difficulties that might occur in the application to particular cases. This was what Bernoulli objected to, and affected to treat the solution as of no value. Brook Taylor, secretary of the Royal Society, and well known as one of the ablest geometers of the time, undertook the defence of it, but concluded with using language very reprehensible, and highly improper to be directed by one man of science against another. Having sufficiently, as he supposed, replied to Bernoulli and his friends, he adds, "if they are not satisfied with the solution, it must be ascribed to *their own ignorance*."[1] It strongly marks the temper by which both sides were now animated, when a man like Taylor, eminent for profound science, and, in general, very much disposed to do justice to the merits of others, should so forget himself as to reproach with ignorance of the calculus, one of the men who understood it the best, and who had contributed the most to its improvement. The irritability and prejudices of Bernoulli admitted of no defence, and he might very well have been accused of viewing the solution of Newton through a medium disturbed by their action; but to suppose that he was unable to understand it, was an impertinence that could only re-act on the person who was guilty of it. Bernoulli was not exemplary for his patience, and it will be readily believed, that the incivility of Taylor was sufficiently revenged. It is painful to see men of science engaged in such degrading altercation, and I should be inclined to turn from so disagreeable an object, if the bad effects of the spirit thus excited were not such as must again obtrude themselves on the notice of the reader.

---

[1] Vol. XXIX. p. 399.

Taylor not long after came forward with an open defiance to the whole Continent, and proposed a problem, *Omnibus geometris non Anglis*,—a problem, of course, which he supposed that the English mathematicians alone were sufficiently enlightened to resolve. He selected one, accordingly, of very considerable difficulty,—the integration of a fluxion of a complicated form; which, nevertheless, admitted of being done in a very elegant manner, known, I believe, at that time to very few of the English mathematicians, to Cotes, to himself, and perhaps, one or two more. The selection, nevertheless, was abundantly injudicious; for Bernoulli, as long ago as 1702, had explained the method of integrating this, and such like formulas, both in the *Paris Memoires* and in the *Leipsic Acts*. The question, accordingly, was no sooner proposed than it was answered in a manner the most clear and satisfactory; so the defiance of Taylor only served to display the address and augment the triumph of his adversary.

---

[1] Eorum imperitiæ tribuendum est.

The last and most unsuccessful of these challenges was that of Keill, of whose former appearance in this controversy we have already had so much more reason to commend the zeal than the discretion. Among the problems in the mixt mathematics which had excited most attention, and which seemed best calculated to exercise the resources of the new analysis, was the determination of the path of a projectile in a medium which resists proportionally to the square of the velocity, that being nearly the law of the resistance which the air opposes to bodies moving with great velocity. The resistance of fluids had been treated of by Newton in the second book of the *Principia,* and he had investigated a great number of curious and important propositions relative to its effects. He had considered some of the simpler laws of resistance, but of the case just mentioned, he had given no solution, and, after approaching as near as possible to it on all sides, had withdrawn without making an attack. A problem so formidable was not likely to meet with many who, even in the more improved state at which the calculus had now arrived, could hope to overcome its difficulties. Whether Keill had flattered himself that he could resolve the problem, or had forgotten, that when a man proposes a question of defiance to another, he ought to be sure that he can answer it himself, may be doubted: but this is certain, that, without the necessary preparation, he boldly challenged Bernoulli to produce a solution.

Bernoulli resolved the question in a very short time, not only for a resistance proportional to the square, but to any power whatsoever of the velocity, and by the conditions which he affixed to the publication of his solution, took care to expose the weakness of his antagonist. He repeatedly offered to send his solution to a confidential person in London, providing Keill would do the same. Keill never made any reply to a proposal so fair, and there could only be one reason for declining it. Bernoulli, of course, exulted over him cruelly, breaking out in a torrent of vulgar abuse, and losing sight of every maxim of candour and good taste.

Such, then, were the circumstances under which the infinitesimal analysis,—the greatest discovery ever made in the mathematical sciences,—was ushered into the world. Every where, as it became known, it enlarged the views, roused the activity, and increased the power of the geometer, while it directed the warmest sentiments of his gratitude and admiration toward the great inventors. In one respect, only, its effects were different from those which one would have wished to see produced. It excited jealousy between two great men who ought to have been the friends of one another, and disturbed in both that philosophic tranquillity of mind, for the loss of which even glory itself is scarcely an adequate recompense.

In order to form a correct estimate of the magnitude and value of this discovery, it may be useful to look back at the steps by which the mathematical sciences had been prepared for it. When we attempt to trace those steps to their origin, we find the principle of the infinitesimal analysis making its first appearance in the method of Exhaustions, as exemplified in the writings of Euclid and Archimedes. These geometers observed, and, for what we know, were the first to observe, that the approach which a rectilineal figure may make to one that is curvilineal, by the increase of the number of its sides, the diminution of their magnitude, and a certain enlargement of the angles they contain, may be such that the properties of the former shall coincide so nearly with those of the latter, that no real difference can be supposed between them without involving a contradiction; and it was in ascertaining the conditions of this approach, and in showing the contradiction to be unavoidable, that the method of Exhaustions consisted. The demonstrations were strictly geometrical, but they were often complicated, always indirect, and of course synthetical, so that they did not explain the means by which they had been discovered.

At the distance of more than two thousand years, Cavalieri advanced a step farther, and, by the sacrifice of some apparent, though of no real accuracy, explained, in the method of indivisibles, a principle which could easily be made to assume the more rigid form of Exhaustions. This was a very important discovery;—though the process was not analytical, the demonstrations were direct, and, when applied to the same subjects, led to the same conclusions which the ancient geometers had deduced; by an indirect proof also, such as those geometers had adopted, it could always be shown that an absurdity followed from supposing the results deduced from the method of indivisibles to be other than rigorously true.

The method of Cavalieri was improved and extended by a number of geometers of great genius who followed him; Torricelli, Roberval, Fermat, Huygens, Barrow, who all observed the great advantage that arose from applying the general theorems concerning variable quantity to the cases where the quantities approached to one another infinitely near, that is, nearer than within any assigned difference.[1] There was, however, as yet, no calculus adapted to these researches, that is, no general method of reasoning by help of arbitrary symbols.

---

[1] Note D, at the end.

But we must go back a step, in point of time, if we would trace accurately the history of this last improvement. Descartes, as has been shown in the former part of this outline, made a great revolution in the mathematical sciences, by applying algebra to the geometry of curves; or, more generally, by applying it to express the relations of variable quantity. This added infinitely to the value of the algebraic analysis, and to the extent of its investigations. The same great mathematician had observed the advantage that would be gained in the geometry of curves, by considering the variable quantities in one state of an equation as differing infinitely little from the corresponding quantities in another state of the same equation. By means grounded on this he had attempted to draw tangents to curves, and to determine their curvature; but it is seldom the destination of Nature that a new discovery should be begun and perfected by the same individual; and, in these attempts, though Descartes did not entirely fail, he cannot be considered as having been successful.[1]

At last came the two discoverers, Newton and Leibnitz, who completely lifted up the veil which their predecessors had been endeavouring to draw aside. They plainly saw, as Descartes indeed had done in part, that the infinitely small variations of the ordinate and absciss are closely connected with many properties of the curve, which have but a very remote dependence on the ordinates and abscissæ themselves. Hence they inferred, that, to obtain an equation expressing the relations of these variations to one another, was to possess the most direct access to the knowledge of those properties. They observed also, that when an equation of this kind was deduced from the general equation, it admitted of being brought to great simplicity, and of being resolved much more readily than the other. In effect, it assumed the form of a simple equation; but, in order to make this deduction in the readiest and most distinct way, the introduction of new symbols, or of a new algorithm, was necessary, the invention of which could cost but little to the creative genius of the men of whom I now speak. They appear, as has been already shown, to have made their discoveries separately;—Newton first,—Leibnitz afterwards, at a considerable interval, yet the earliest, by several years, in communicating his discoveries to the world.

Thus, though there had been for ages a gradual approach to the new analysis, there were in that progress some great and sudden advances which elevated those who made them to a much higher level than their predecessors. A great number of individuals co-operated in the work; but those who seem essential, and in the direct line of advancement, are Euclid, Cavalieri, Descartes, Newton and Leibnitz. If any of the others had been wanting, the world would have been deprived of many valuable theorems, and many collateral improvements, but not of any general method essential to the completion of the infinitesimal analysis.

---

[1] Dissert. Second, Part I. p. 18.

The views, however, of this analysis taken by the two inventors were not precisely the same. Leibnitz, considering the differences of the variable quantities as infinitely small, conceived that he might reject the higher powers of those differences without any sensible error; so that none of those powers but the first remained in the differential equation finally obtained. The rejection, however, of the higher powers of the differentials was liable to objection, for it had the appearance of being only an approximation, and did not come up to the perfect measure of geometrical precision. The analysis, thus constituted, necessarily divided itself into two problems;—the first is,—having given an equation involving two or more variable quantities, to find the equation expressing the relation of the differentials, or infinitely small variations of those quantities; the second is the converse of this;—having given an equation involving two or more variable quantities, and their differentials, to exterminate the differentials, and so to exhibit the variable quantities in a finite state. This last process is called *integration* in the language of the differential analysis, and the finite equation obtained is called the *integral* of the given differential equation.

Newton proceeded in some respects differently, and so as to preserve his calculus from the imputation of neglecting or throwing away any thing merely because it was small. Instead of the actual increments of the flowing or variable quantities, he introduced what he called the fluxions of those quantities,—meaning, by fluxions, quantities which had to one another the same ratio which the increments had in their ultimate or evanescent state. He did not reject quantities, therefore, merely because they were so small that he *might* do so without committing any sensible error, but because he *must* reject them, in order to commit no error whatsoever. Fluxions were, with him, nothing else than measures of the velocities with which variable or flowing quantities were supposed to be generated, and they might be of any magnitude, providing they were in the ratio of those velocities, or, which is the same, in the ratio of the nascent or evanescent increments.[1] The fluxions, therefore, and the flowing quantities or fluents of Newton correspond to the differentials and the sums or integrals of Leibnitz; and though the symbols which denote fluxions are different from those used to express differentials, they answer precisely the same purpose. The fluxionary and differential calculus may therefore be considered as two modifications of one general method, aptly distinguished by the name of the *infinitesimal analysis.*

---

[1] "I consider mathematical quantities in this place not as consisting of small parts, but as described by a

By the introduction of this analysis, the domain of the mathematical sciences was incredibly enlarged in every direction. The great improvement which Descartes had made by the application of algebraic equations to define the nature of curve lines was now rendered much more efficient, and carried far beyond its original boundaries. From the equation of the curve the new analysis could deduce the properties of the tangents, and, what was much more difficult, could go back from the properties of the tangents to the equation of the curve. From the same equation it was able to determine the curvature at every point; it could measure the length of any portion of the curve or the area corresponding to it. Nor was it only to algebraic curves that those applications of the calculus extended, but to curves transcendental and mechanical, as in the instances of the catenaria, the cycloid, the elastic curve, and many others. The same sort of research could be applied to curve surfaces described according to any given law, and also to the solids contained by them.

The problems which relate to the *maxima* and *minima*, or the greatest and least values of variable quantities, are among the most interesting in the mathematics; they are connected with the highest attainments of wisdom and the greatest exertions of power; and seem like so many immoveable columns erected in the infinity of space, to mark the eternal boundary which separates the regions of possibility and impossibility from one another. For the solution of these problems, a particular provision seemed to be made in the new geometry.

When any function becomes either the greatest or the least, it does so by the velocity of its increase or of its decrease ceasing entirely, or in the language of algebra, becoming equal to nothing. But when the velocity with which the function varies becomes nothing, the fluxion which is proportional to that velocity must become nothing also. Therefore, it is only necessary to take the fluxion of the given function, and by supposing it equal to nothing, an equation will be obtained in finite terms

---

continued motion. Lines are described and thereby generated, not by the apposition of parts, but by the continued motion of points, superfices by the motion of lines," &c.—*Quadrature of Curves*, Introduction.

(for the fluxion will entirely disappear), expressing the relation of the quantities when the function assigned is the greatest or the least possible.

Another kind of maximum or minimum, abounding also in interesting problems, is more difficult by far than the preceding, and, when taken generally, seems to be only accessible to the new analysis. Such cases occur when the function of the variable quantities which is to be the greatest or the least is not given, but is itself the thing to be found; as when it is proposed to determine the line by which a heavy body can descend in the least time from one point to another. Here the equation between the co-ordinates of the curve to be found is, of course, unknown, and the function of those co-ordinates which denotes the time of descent cannot therefore be algebraically expressed, so that its fluxion cannot be taken in the ordinary way, and thus put equal to nothing. The former rule, then, is not applicable in such cases, and it is by no means obvious in what manner this difficulty is to be overcome. The general problem exercised the ingenuity of both the Bernoullis, as it has since done of many other mathematicians of the greatest name. As there are in such problems always two conditions, according to the first of which, a certain property is to remain constant, or to belong to all the individuals of the species, and according to the second, another property is to be the greatest or the least possible: and as, in some of the simplest of such questions,[1] the constant quantity is the circumference or perimeter of a certain curve, so problems of this kind have had the name of *Isoperimetrical* given them, a term which has thus come to denote one of the most curious and difficult subjects of mathematical investigation.

The new analysis, especially, according to the view taken of it by Newton, is peculiarly adapted to physical researches, as the hypothesis of quantities being generated by continued motion, comes there to coincide exactly with the fact. The momentary increments or the fluxions represent so precisely the forces by which the changes in nature are produced, that this doctrine seemed created for the express purpose of penetrating into the interior of things, and taking direct cognizance of those animating powers which, by their subtilty, not only elude the observation of sense, but the ordinary methods of geometrical investigation. The infinitesimal analysis alone affords the means of measuring forces, when each acts separately, and instantaneously under conditions that can be accurately ascertained. In comparing the effects of continued action, the variety of time and circumstance, and the continuance of effects after their causes have ceased, introduce so much uncertainty, that nothing but vague and unsatisfactory conclusions can be deduced. The analysis of infinites goes directly to the point; it measures the intensity or instantaneous effort of the force, and, of course, removes all those causes of uncertainty which prevailed when the results of *continued* action could alone be estimated. It is not even by the effects produced in a short time, but by effects taken in their *nascent* or *evanescent* state, that the true proportion of causes must be ascertained.

---

[1] The most simple problem of the kind is strictly and literally *Isoperimetrical*, viz. of all curves having the same perimeter to find that which has the greatest area. Elementary geometry had pronounced this curve to be the circle long before there was any idea of an entire class of problems characterized by similar conditions. *Vid. Pappi Alexandrini Collect. Math.* Lib. V. Prop. 2, &c.

Thus, though the astronomers had proved that the planets describe ellipses round the sun as the common focus, and that the line from the sun to each planet sweeps over areas proportional to the time; had not the geometer resolved the elliptic motion into its primary elements, and compared them in their state of evanescence, it would never have been discovered that these bodies gravitate to the sun with forces which are inversely as the square of their distances from the centre of that luminary. Thus, fortunately, the first discovery of Newton was the instrument which was to conduct him safely through all the intricacies of his future investigations.

The calculus, as already remarked, necessarily divides itself into two branches; one which, from the variable quantities, finds the relation of their fluxions or differentials; another which, from the relation of these last, investigates the relation of the variable quantities themselves. The first of these problems is always possible, and, in general, easy to be resolved; the second is not always possible, and when possible, is often very difficult, but in various degrees, according to the manner in which the differentials and the variable quantities are combined with one another.

If the function, into which the differential stands multiplied, consist of a single term, or an aggregate of terms, in each of which the variable quantity is raised to a power expounded by a number positive, negative, or fractional, the integration can be effected with ease, either in algebraic or logarithmic terms; and the calculus had not been long known before this problem was completely resolved.

The second case of this first division is, when the given function is a fraction having a binomial or multinomial denominator, the terms of which contain any powers whatever of the variable magnitude, but without involving the radical sign. If the denominator contain only the simple power of the variable quantity, the integral is easily found by logarithms; if it be complex, it must be resolved either into simple or quadratic divisors, which, granting the solution of equations, is always possible, at least by approximation, and the given fraction is then found equal to an aggregate of simple fractions, having these divisors for their denominators, and of which the fluents can always be exhibited in algebraic terms, or in terms of logarithms and circular arches. This very general and important problem was resolved by J. Bernoulli as early as the year 1702.

The denominator is in this last case supposed rational; but if it be irrational, the integration requires other means to be employed. Here Leibnitz and Bernoulli both taught, how, by substitutions, as in *Diophantine* problems, the irrationality might be removed, and the integration of course reduced to the former case. Newton employed a different method, and, in his *Quadrature of Curves*, found the fluents, by comparing the given fluxion with the formulas immediately derived from the expression of circular or hyperbolic areas. The integrations of these irrational formulæ, whichever of the methods be employed, often admit of being effected with singular elegance and simplicity; but a general integration of all the formulæ of this kind, except by approximation, is not yet within the power of analysis.

The second general division of the problem of integration, viz. when the two variable quantities and their differentials are mixed together on each side of the equation, is a more difficult subject of inquiry than the preceding. It may indeed happen, that an equation, which at first presents itself under this aspect, can, by the common rules of algebra, have the quantities so separated, that on each side of the sign of equality there shall be but one variable quantity with its fluxion; and when this is done, the integration is reduced to one of the cases already enumerated.

When such separation cannot be made, the problem is among the most difficult which the infinitesimal analysis presents, at the same time that it is the key to a vast number of interesting questions both in the pure and the mixed mathematics. The two Bernoullis applied themselves strenuously to the elucidation of it; and to them we owe all the best and most accurate methods of resolving such questions which appeared in the early history of the calculus, and which laid the foundation of so many subsequent discoveries. This is a fact which cannot be contested: and it must be acknowledged also, that, on the same subject, the writings of the English mathematicians were then, as they continue to be at this day, extremely defective. Newton, though he had treated of this branch of the infinitesimal analysis with his usual ingenuity and depth, had done so only in his work on *Fluxions*, which did not see the light till several years after his death, when, in 1736, it appeared in Colson's translation. But that work, even had it come into the hands of the public in the author's lifetime, would not have remedied the defect of which I now speak. When the fluxionary equation could not be integrated by the simplest and most elementary rules, Newton had always recourse to approximations by infinite series, in the contrivance of which he indeed displayed great ingenuity and address. But an approximation, let it be ever so good, and converge ever so rapidly, is always inferior to an accurate and complete solution, if this last possess any tolerable degree of simplicity. The series which affords the approximation cannot converge always, or in all states of the variable quantity; and its utility, on that account, is so much limited, that it can hardly lead to any general result. Besides, it does not appear that these series can always be made to involve the arbitrary or indeterminate quantity, without which no fluent can be considered as complete. For these reasons, such approximations should never be resorted to till every expedient has been used to find an accurate solution. To this rule, however, Newton's method does not conform, but employs approximation in cases where the complete integral can be obtained. The tendency of that method, therefore, however great its merit in other respects, was to give a direction to research which was not always the best, and which, in many instances, made it fall entirely short of the object it ought to have attained. It is true, that many fluxionary equations cannot be integrated in any other way; but by having recourse to it indiscriminately, we overlook the cases in which the integral can be exactly assigned. Accordingly, Bernoulli, by following a different process, remarked entire classes of fluxionary or differential equations, that admitted of accurate integration. Thus he found, that differential equations, if homogeneous,[1] however complicated, may always have the variable quantities separated, so as to come under one of the simpler forms already enumerated. By the introduction, also, of exponential equations, which had been considered in England as of little use, he materially improved this branch of the calculus.

To all these branches of analysis we have still another to add of indefinite extent, arising out of the consideration of the fluxions or differentials of the higher orders, each of these orders being deduced from the preceding, just as first fluxions are from the variable quantities to which they belong. To understand this, conceive the successive values of the first fluxions of any variable quantity to constitute a new series of variable quantities flowing with velocities, the measures of which form the fluxions of the second order, from which, in the same manner, are deduced fluxions of the third and of still higher orders. The general principles are the same as in the fluxions of the first order, but the difficulties of the calculus are greater, particularly in the integrations; for to rise from second fluxions to the variable quantities themselves two integrations are necessary; from third fluxions three, and so on.

---

[1] Homogeneous equations in the differential calculus, are those in which the sum of the exponents of the variable quantities is the same in all the terms.

The tract which first made known the new analysis was that of Leibnitz, published, as already remarked, in the first volume of the *Acta Eruditorum* for 1684, where it occupies no more than six pages,[1] and is the work of an author not yet become very familiar with the nature of his own invention. It was sufficient, however, to explain that invention to mathematicians; but, nevertheless, some years elapsed before it drew much attention. The Bernoullis were the first who perceived its value, and made themselves masters of the principles and methods contained, or rather suggested, in it. Leibnitz published many other papers in the *Acta Eruditorum* and the journals of the times, full of original views and important hints, thrown out very briefly, and requiring the elucidations which his friends just mentioned were always so willing and so able to supply. The number of literary and scientific objects which divided the attention of the author himself was so great, that he had not time to bestow on the illustration and developement of the most important of his own discoveries; and the new analysis, for all that he has taught, would have been very little known, and very imperfectly unfolded, if the two excellent geometers just named had not come to his assistance. Their tracts were also, like his, scattered in the different periodic works of that time, and several years elapsed before any elementary treatise explained the general methods, and illustrated them by examples. The first book in which this was done, so far at least as concerned the differential or direct calculus, was the *Analyse des Infiniment Petits* of the *Marquis de l'Hôpital,* published in 1696, a work of great merit, which did much to diffuse the knowledge of the new analysis. It was well received at that time, and has maintained its character to the present day. The author, a man of genius, indefatigable and ardent in the pursuits of science, had enjoyed the *viva voce* instructions of John Bernoulli, on the subject of the new geometry, and therefore came forward with every possible advantage.

It was long after this before the works of the Bernoullis were collected together, those of James in two quarto volumes, and of John in four.[1] In the third of these last volumes is a tract of considerable length, with the title of *Lectiones de Methodo Integralium,* written in 1691 and 1692, for the use of M. de l'Hôpital, to whose book on the differential calculus it seems to have been intended as a sequel. It is a work of great merit; and affords a distinct view of many of the most general methods of integration, with their application to the most interesting problems; so that, though the earliest treatise on that subject, it remains at this day one of the best compends of the new analysis of which the mathematical world is in possession. Indeed, the whole of the volumes just referred to are highly interesting, as containing the original germs of the new analysis, and as being the work of men always inspired by genius, sometimes warmed by opposition, and generally animated by the success which accompanied their researches.

---

[1] *Nova Methodus pro Maximis et Minimis,* &c. Leibnitii *Opera,* Tom. III. p. 167.

But we must now look at the original works of the earliest inventor. Newton, besides his letters published in the *Commercium Epistolicum,* is the author of three tracts on the new analysis that have all been occasionally mentioned. None of them, however, appeared nearly so soon as a great number of the pieces which have just been enumerated. The *Quadrature of Curves,* written as early as 1665 or 1666, did not appear till 1704; and though it be a treatise of great value, and containing very important and very general theorems concerning the quadrature of curves, it must be allowed, that it is not well adapted to make known the spirit and the views of the infinitesimal analysis. After a short introduction, which is indeed analytical, and which explains the idea of a fluxion with great brevity and clearness, the treatise sets out with proposing to find any number of curves that can be squared; and here the demonstrations become all synthetical, without any thing that may be properly called analytical investigation. By synthetical demonstrations I do not mean reasonings where the algebraic language is not used, but reasonings, whatever language be employed, where the solution of the proposed question is first laid down, and afterwards demonstrated to be true. Such is the method pursued throughout this work, and it is wonderful how many valuable conclusions concerning the areas of curves, and their reduction to the areas of the circle and hyperbola, are in that manner deduced. But though truths can be very well conveyed in the synthetical way, the methods of investigating truth are not communicated by it, nor the powers of invention directed to their proper objects. As an elementary treatise on the new analysis, the *Quadrature of Curves* is therefore imperfect, and not calculated, without great study, to give to others any portion of the power which the author himself has exerted. The problem of finding fluents, though it be that on which the whole quadrature of curves depends, is entirely kept out of view, and never once proposed in the course of a work, which, at the same time, is full of the most elaborate and profound reasonings.

---

[1] Those of James were published at Geneva in 1744; of John at Lausanne and Geneva in 1742.

Newton had a great fondness for the synthetical method, which is apparent even in the most analytical of his works. In his *Fluxions*, when he is treating of the quadrature of curves, he says, " After the area of a curve has been found and constructed, we should consider about the demonstration of the construction, that, laying aside all algebraical calculation, as much as may be, the theorem may be adorned and made elegant, so as to become fit for public view."[1] This is followed by two or three examples, in which the rule here given is very happily illustrated. When the analysis of a problem requires, like the quadrature of curves, the use of the inverse method of fluxions, the reversion of that analysis, or the synthetical demonstration, must proceed by the direct method, and therefore may admit of more simplicity than the others, so as, in the language of the above passage, to be easily adorned and made elegant.

The book of *Fluxions* is, however, an excellent work, entering very deeply into the nature and spirit of the calculus,—illustrating its application by well chosen examples,—and only failing, as already said, by having recourse, for finding the fluents of fluxionary equations, too exclusively to the method of series, without treating of the cases in which exact solutions can be obtained.

Of the works that appeared in the early stages of the calculus, none is more entitled to notice than the *Harmonia Mensurarum* of Cotes. The idea of reducing the areas of curves to those of the circle and hyperbola, in those cases which did not admit of an accurate comparison with rectilineal spaces, had early occurred to Newton, and was very fully exemplified in his *Quadrature of Curves*. Cotes extended this method:—his work appeared, in 1722, and gave the rules for finding the fluents of fractional expressions, whether rational or irrational, greatly generalized and highly improved by means of a property of the circle discovered by himself, and justly reckoned among the most remarkable propositions in geometry. It is singular that a work so profound, and so useful as the *Harmonia Mensurarum*, should never have acquired even among the mathematicians of England, the popularity which it deserves; and that, on the Continent, it should be very little known, even after the excellent commentary and additions of Bishop Walmsley. The reasons, perhaps, are, that, in many parts, the work is obscure; that it does not explain the analysis which must have led to the *formulæ* contained in the tables; and that it employs an unusual language and notation, which, though calculated to keep in view the analogy between circular and hyperbolic areas, or between the measures of angles and of ratios, do not so readily accommodate themselves to the business of calculation as those which are commonly in use. Demoivre, a very skilful and able mathematician, improved the method of Cotes; and explained many things in a manner much more clear and analytical than had hitherto been done.[1]

---

[1] Newton's *Fluxions*, Colson's Translation, p. 116, § 107.

Another very original and profound writer of this period was Brook Taylor, who has already been often mentioned, and who, in his *Method of Increments*, published in 1715, added a new branch to the analysis of variable quantity. According to this method, quantities are supposed to change, not by infinitely small, but by finite increments, or such as may be of any magnitude whatever. There are here, therefore, as in the case of fluxions or differentials, two general questions: A function of a variable quantity being given, to find the expression for the finite increment of that function, the increment of the variable quantity itself being a finite magnitude. This corresponds to the direct method of fluxions; the other question corresponds to the inverse, viz. A function being given containing variable quantities, and their increments any how combined, to find the function from which it is derived. The author has considered both these problems, and in the solution of the second, paticularly, has displayed much address. He has also made many ingenious applications of this calculus both to geometrical and physical questions, and, above all, to the summation of series, a problem for the solution of which it is peculiarly adapted.

Taylor, however, was more remarkable for the ingenuity and depth, than for the perspicuity of his writings; even a treatise on *Perspective*, of which he is the author, though in other respects excellent, has always been complained of as obscure; and it is no wonder if, on a new subject, and one belonging to the higher geometry, his writings should be still more exposed to that reproach. This fault was removed, and the whole theory explained with great clearness, by M. Nicol, of the Academy of Sciences of Paris, in a series of *Memoires* from the year 1717 to 1727.

---

[1] Demoivre, *Miscellanea Analytica.* See also the work of an anonymous author, *Epistola ad Amicum de Cotesii Inventis.*

A single analytical formula in the *Method of Increments* has conferred a celebrity on its author, which the most voluminous works have not often been able to bestow. It is known by the name of Taylor's Theorem, and expresses the value of any function of a variable quantity in terms of the successive orders of increments, whether finite or infinitely small. If any one proposition can be said to comprehend in it a whole science it is this: for from it almost every truth and every method of the new analysis may be deduced. It is difficult to say, whether the theorem does most credit to the genius of the author, or the power of the language which is capable of concentrating such a vast body of knowledge in a single expression. Without an acquaintance with algebra, it is impossible, I believe, to conceive the manner in which this effect is produced.

By means of its own intrinsic merit, and the advantageous display of it made in the works now enumerated, the new analysis, long before the expiration of the period of which I am here treating, was firmly established all over Europe. It did not, however, exist everywhere in the same condition, nor under the same form; with the British and Continental mathematicians, it was referred to different origins; it was in different states of advancement; the notation and some of the fundamental ideas were also different. The authors communicated little with one another, except in the way of defiance or reproach; and, from the angry or polemical tone which their speculations often assumed, one could hardly suppose, that they were pursuing science in one of its most abstract and incorporeal forms.

Though the algorithm employed, and the books consulted on the new analysis, were different, the mathematicians of Britain and of the Continent had kept pace very nearly with one another during the period now treated of, except in one branch, the integration of differential or of fluxional equations. In this, our countrymen had fallen considerably behind, as has been already explained; and the distance between them and their brethren on the Continent continued to increase, just in proportion to the number and importance of the questions, physical and mathematical, which were found to depend on these integrations. The habit of studying only our own authors on these subjects, produced at first by our admiration of Newton and our dislike to his rivals, and increased by a circumstance very insignificant in itself, the diversity of notation, prevented us from partaking in the pursuits of our neighbours; and cut us off in a great measure from the vast field in which the genius of France, of Germany, and Italy, was exercised with so much activity and success. Other causes may have united in the production of an effect, which the mathematicians of this country have had much reason to regret; but the evil had its origin in the spirit of jealousy and opposition, which arose from the controversies that have just passed under our review. The habits so produced continued long after the spirit itself had subsided.

It must not be supposed, that so great a revolution in science, as that which was made by the introduction of the new analysis, could be brought about entirely without opposition, as in every society there are some who think themselves interested to maintain things in the condition wherein they have found them. The considerations are indeed sufficiently obvious, which, in the moral and political world, tend to produce this effect, and to give a stability to human institutions, often so little proportionate to their real value or to their general utility. Even in matters purely intellectual, and in which the abstract truths of arithmetic and geometry seem alone concerned, the prejudices, the selfishness, or vanity of those who pursue them, not unfrequently combine to resist improvement, and often engage no inconsiderable degree of talent in drawing back instead of pushing forward the machine of science. The introduction of methods entirely new must often change the relative place of the men engaged in scientific pursuits; and must oblige many, after descending from the stations they formerly occupied, to take a lower position in the scale of intellectual advancement. The enmity of such men, if they be not animated by a spirit of real candour and the love of truth, is likely to be directed against methods, by which their vanity is mortified, and their importance lessoned. Though such changes as this must have everywhere accompanied the ascendancy acquired by the calculus, for the credit of mathematicians it must be observed, that no one of any considerable eminence has had the misfortune to enrol his name among the adversaries of the new science; and that Huygens, the most distinguished and most profound of the older mathematicians then living, was one of the most forward to acknowledge the excellence of that science, and to make himself master of its rules, and of their application.

Nevertheless, certain adversaries arose successively in Germany, France, and England, the countries in which the new methods first became known.

Nieuentit, an author commendable as a naturalist, and as a writer on morals, but a very superficial geometer, aimed the first blow at the Differential Calculus. He objected to the explanation of Leibnitz, and to the notion of quantities infinitely small.[1] It seemed as if he were unwilling to believe in the reality of objects smaller than those discovered by his own microscope, and were jealous of any one who should come nearer to the limit of extension than he himself had done. Leibnitz thought his objections not undeserving of a reply; but the reply was not altogether satisfactory. A second was given with better success; and afterwards Herman and Bernoulli each severally defeated an adversary, who was but very ill able to contend with either of them.

Soon after this, the calculus had to sustain an attack from two French academicians, which drew more attention than that of the Dutch naturalist. One of these, Rolle, was a mathematician of no inconsiderable acquirement, but whose chief gratification consisted in finding out faults in the works of others. He founded his objections to the differential calculus, not on the score of principles or of general methods, but on certain cases which he had sought out with great industry, in which those methods seemed to him to lead to false and contradictory conclusions. On examination, however, it turned out, that in every one of those instances the error was entirely his own; that he had misapplied the rules, and that his eagerness to discover faults had led him to commit them. His errors were detected and pointed out with demonstrative evidence by Varignon, Saurin, and some others, who were among the first to perceive the excellence and to defend the solidity of the new geometry. These disputes were of consequence enough to occupy the attention of the Academy of Sciences during a great part of the year 1701.

The Abbé Gallois joined with Rolle in his hostility to the calculus, and though he added very little to the force of the attack, he kept the field after the other had retired from the combat. Fontenelle, in his *Eloge* on the Abbé, has given an elegant turn to the apology he makes for him.—"His taste for antiquity made him suspicious of the geometry of infinites. He was, in general, no friend to any thing that was new, and was always prepared with a kind of *Ostracism* to put down whatever appeared too conspicuous for a free state like that of letters. The geometry of infinites had both these faults, and particularly the latter."

After all these disputes were quieted in France, and the new analysis appeared completely victorious, it had an attack to sustain in England from a more formidable quarter, Berkeley, Bishop of Cloyne, was a man of first rate talents, distinguished as a metaphysician, a philosopher, and a divine. His geometrical knowledge, however, which, for an attack on the method of fluxions, was more essential than all his other accomplishments, seems to have been little more than elementary. The motive which induced him to enter on discussions so remotely connected with his usual pursuits has been variously represented; but, whatever it was, it gave rise to the *Analyst*, in which the author professes to demonstrate, that the new analysis is inaccurate in its principles, and that, if it ever lead to true conclusions, it is from an accidental compensation of errors that cannot be supposed always to take place. The argument is ingeniously and plausibly conducted, and the author sometimes attempts ridicule with better success than could be expected from the subject; thus, when he calls ultimate ratios the *ghosts of departed quantities*, it is not easy to conceive a witty saying more happily fastened on a mere mathematical abstraction.

---

[1] He published *Analysis Infinitorum* at Amsterdam, in 1695; and another tract, *Considerationes circa Calculi Differentialis Principia*, in the year following. This last was answered by Herman.

The *Analyst* was answered by Jurin, under the signature of *Philalethes;* and to this Berkeley replied in a tract entitled *A Defence of Freethinking in Mathematics*. Replies were again made to this, so that the argument assumed the form of a regular controversy; in which, though the defenders of the calculus had the advantage, it must be acknowledged that they did not always argue the matter quite fairly, nor exactly meet the reasoning of their adversary. The true answer to Berkeley was, that what he conceived to be an accidental compensation of errors was not at all accidental, but that the two sets of quantities that seemed to him neglected in the reasoning were in all cases necessarily equal, and an exact balance for one another. The Newtonian idea of a fluxion contained in it this truth, and so it was argued by Jurin and others, but not in a manner so logical and satisfactory as might have been expected. Perhaps it is not too much to assert, that this was not completely done till La Grange's *Theory of Functions* appeared. Thus, if the author of the *Analyst* has had the misfortune to enrol his name on the side of error, he has also had the credit of proposing difficulties of which the complete solution is only to be derived from the highest improvements of the calculus.

This controversy made some noise in England, but I do not think that it ever drew much attention on the Continent. The *Analyst*, I imagine, notwithstanding its acuteness, never crossed the Channel. Montucla evidently knows it only by report, and seems as little acquainted with the work as with its author, of whom he speaks very slightly, and supposes he has sufficiently described him by saying, that he has written a book against the existence of matter, and another in praise of tar-water. But it is less from the opinions which men support than from the manner in which they support them, that their talents are to be estimated. If we judge by this criterion, we shall pronounce Berkeley to be a man of genius, whether he be employed in attacking the infinitesimal analysis, in disproving the existence of the external world, or in celebrating the virtues of tar-water.[1]

SECTION II.

MECHANICS, GENERAL PHYSICS, &c.

THE discoveries of Galileo, Descartes, and other mathematicians of the seventeenth century, had made known some of the most general and important laws which regulate the phenomena of moving bodies. The inertia, or the tendency of body, when left to itself, to preserve unchanged its condition either of motion or of rest; the effect of an impulse communicated to a body, or of two simultaneous impulses, had been carefully examined, and had led to the discovery of the composition of motion. The law of equilibrium, not in the lever alone, but in all the mechanical powers, had been determined, and the equality of action to re-action, or of the motion lost to the motion acquired, had not only been established by reasoning, but confirmed by experiment. The fuller elucidation and farther extension of these principles were reserved for the period now treated of.

The developement of truth is often so gradual, that it is impossible to assign the time when certain principles have been first introduced into science. Thus, the principle of *Virtual Velocities*, as it is termed, which is now recognized as regulating the equilibrium of all machines whatsoever, was perceived to hold in particular cases long before its full extent, or its perfect universality, was understood. Galileo made a great step toward the establishment of this principle when he generalized the property of the lever, and showed, that an equilibrium takes place whenever the sums of the opposite *momenta* are equal, meaning by momentum the product of the force into the velocity of the point at which it is applied. This was carried farther by Wallis, who appears to have been the first writer who, in his *Mechanica*, published in 1669, founded an entire system of statics on the principle of Galileo, or the equality of the opposite momenta. The proposition, however, was first enunciated in its full generality, and with perfect precision,[1] by John Bernoulli, in a letter to Varignon, so late as the year 1717. Varignon inserted this letter at the end of the second edition of his *Projet d'une Nouvelle Mecanique*, which was not published till 1725. The first edition of the same book appeared in 1687, and had the merit of deriving the whole theory of the equilibrium of the mechanical powers, from the single principle of the composition of forces. At first sight, there appear in mechanics two independent principles of equilibrium, that of the lever, or of equal and opposite momenta, and that of the composition of forces. To show that these coincide, and that the one may be deduced from the other, is, therefore, doing a service to science, and this the ingenious author just named accomplished by help of a property of the parallelogram, which he seems to have been the first who demonstrated.

---

[1] Though Berkeley reasons very plausibly, and with considerable address, he hurts his cause by the comparison so often introduced between the mysteries of religion and what he accounts the mysteries of the new geometry. From this it is natural to infer, that the author is avenging the cause of religion on the infidel mathematician to whom his treatise is addressed; and an argument that is suspected to have any other object than that at which it is directly aimed, must always lose somewhat of its weight.

The dispute here mentioned did not take place till about the year 1734; so that I have here treated of it by anticipation, being unwilling to resume the subject of controversies which, though perhaps useful at first for the purpose of securing the foundations of science, are long since set to rest, and never likely to be revived.

The *Principia Mathematica* of Newton, published also in 1687, marks a great era in the history of human knowledge, and had the merit of effecting an almost entire revolution in mechanics, by giving new powers and a new direction to its researches. In that work the composition of forces was treated independently of the composition of motion, and the equilibrium of the lever was deduced from the former, as well as in the treatise already mentioned. From the equality of action and re-action it was also inferred, that the state of the centre of gravity of any system of bodies, is not changed by the action of those bodies on one another. This is a great proposition in the mechanics of the universe, and is one of the steps by which that science ascends from the earth to the heavens; for it proves that the quantity of motion existing in nature, when estimated in any one given direction, continues always of the same amount.

---

[1] The principle of Virtual Velocities may be thus enunciated: If a system of bodies be in a state of equilibrium, in consequence of the action of any forces whatever, on certain points in the system; then were the equilibrium to be for a moment destroyed, the small space moved over by each of these points will express the virtual velocity of the power applied to it, and if each force be multiplied into its virtual velocity, the sum of all the products where the velocities are in the same direction, will be equal to the sum of all those in which they are in the opposite.

The distinction between actual and virtual velocities was first made by Bernoulli, and is very essential to thinking as well as to speaking with accuracy on the nature of equilibriums.

But the new applications of mechanical reasoning,—the reduction of questions concerning force and motion to questions of pure geometry,—and the mensuration of mechanical action by its nascent effects,—are what constitute the great glory of the *Principia*, considered as a treatise on the theory of motion. A transition was there made from the consideration of forces acting at stated intervals, to that of forces acting continually,—and from forces constant in quantity and direction to those that converge to a point, and vary as any function of the distance from that point; the proportionality of the areas described about the centre of force, to the times of their description; the equality of the velocities generated in descending through the same distance by whatever route; the relation between the squares of the velocities produced or extinguished, and the sum of the accelerating or retarding forces, computed with a reference, not to the time during which, but to the distance over which they have acted. These are a few of the mechanical and dynamical discoveries contained in the same immortal work; a fuller account of which belongs to the history of physical astronomy.

The end of the seventeenth and the beginning of the eighteenth centuries were rendered illustrious, as we have already seen, by the mathematical discoveries of two of the greatest men who have ever enlightened the world. A slight sketch of the improvements which the theory of mechanics owes to Newton has been just given; those which it owes to Leibnitz, though not equally important nor equally numerous, are far too conspicuous to be passed over in silence. So far as concerns general principles they are reduced to three,—the argument of the sufficient reason,—the law of continuity,—and the measurement of the force of moving bodies by the square of their velocities; which last, being a proposition that is true or false according to the light in which it is viewed, I have supposed it placed in that which is most favourable.

With regard to the first of these,—*the principle of the sufficient reason,*—according to which, nothing exists in any state without a reason determining it to be in that state rather than in any other,—though it be true that this proposition was first distinctly and generally announced by the philosopher just named, yet is it certain that, long before his time, it had been employed by others in laying the foundations of science. Archimedes and Galileo had both made use of it, and perhaps there never was any attempt to place the elementary truths of science on a solid foundation in which this principle had not been employed. We have an example of its application in the proof usually given, that a body in motion cannot change the direction of its motion, abstraction being made from all other bodies, and from all external action; for it is evident, that no reason exists to determine the change of motion to be in one direction more than another, and we therefore conclude that no such change can possibly take place. Many other instances might be produced where the same principle appears as an axiom of the clearest and most undeniable evidence. Wherever, indeed, we can pronounce with certainty that the conditions which determine two different things, whether magnitudes or events, are in two cases precisely the same, it cannot be doubted that these events or magnitudes are in all respects identical.

However sound this principle may be in itself, the use which Leibnitz sometimes made of it has tended to bring it into discredit. He argued, for example, that of the particles of matter no two can possess exactly the same properties, or can perfectly resemble one another, otherwise the Supreme Being could have no reason for employing one of them in a particular position more than another, so that both must necessarily be rejected. To argue thus, is to suppose that we completely understand the manner in which motives act on the mind of the Divinity,[1] a postulate that seems but ill suited to the limited sphere of the human understanding. But, if Leibnitz has misapplied his own principle and extended its authority too far, this affords no ground for rejecting it when we are studying the ordinary course of nature, and arguing about the subjects of experiment and observation. In fact, therefore, the sciences which aspire to place their foundation on the solid basis of necessary truth, are much indebted to Leibnitz for the introduction of this principle into philosophy.

Another principle of great use in investigating the laws of motion, and of change in general, was brought into view by the same author,—*the law of Continuity*,—according to which, nothing passes from one state to another without passing through all the intermediate states. Leibnitz considers himself as the first who made known this law; but it is fair to remark, that, in as much as motion is concerned, it was distinctly laid down by Galileo,[2] and ascribed by him to Plato. But, though Leibnitz was not the first to discover the law of continuity, he was the first who regarded it as a principle in philosophy, and used it for trying the consistency of theories, or of supposed laws of nature, and the agreement of their parts with one another. It was in this way that he detected the error of Descartes's conclusions concerning the collision of bodies, showing, that though one case of collision must necessarily graduate into another, the conclusions of that philosopher did by no means pass from one to another by such gradual transition. Indeed, for the purpose of such detections, the knowledge of this law is extremely useful; and I believe few have been much occupied in the investigations either of the pure or mixed mathematics, who have not often been glad to try their own conclusions by the test which it furnishes.

---

[1] The argument of Leibnitz seems evidently inconclusive. For, though there were two similar and equal atoms, yet as they could not co-exist in the same space, they would not, so far as position is concerned, bear the same relation to the particles that surrounded them; there might exist, therefore, considering them as part of the materials to be employed in the construction of the universe, very good reasons for assigning different situations to each.

[2] *Opere di Galileo*, Tom. III. p. 150, and Tom. II. p. 32. Edit. Padova, 1744.

Leibnitz considered this principle as known *à priori*, because if any *saltus* were to take place, that is, if any change were to happen without the intervention of time, the thing changed must be in two different conditions at the same individual instant, which is obviously impossible. Whether this reasoning be quite satisfactory or not, the conformity of the law to the facts generally observed, cannot but entitle it to great authority in judging of the explanations and theories of natural phenomena.

It was the usual error, however, of Leibnitz and his followers, to push the metaphysical principles of science into extreme cases, where they lead to conclusions to which it was hardly possible to assent. The Academy of Sciences at Paris having proposed as a prize question, the Investigation of the Laws of the Communication of Motion,[1] John Bernoulli presented an Essay on the subject, very ingenious and profound, in which, however, he denied the existence of hard bodies, because, in the collision of such bodies, a finite change of motion must take place in an instant, an event which, on the principle just explained, he maintained to be impossible. Though the Essay was admired, this conclusion was objected to, and D'Alembert, in his *Eloge* on the author, remarks, that, even in the collision of elastic bodies, it is difficult to conceive how, among the parts which first come into contact, a sudden change, or a change *per saltum*, can be avoided. Indeed, it can only be avoided by supposing that there is no real contact, and that bodies begin to act upon one another when their surfaces, or what seems to be their surfaces, are yet at a distance.

Maclaurin and some others are disposed, on account of the argument of Bernoulli, to reject the law of continuity altogether. This, however, I cannot help thinking, is to deprive ourselves of an auxiliary that, under certain restrictions, may be very useful in our researches, and is often so, even to those who profess to reject its assistance. It is admitted that the law of continuity generally leads right, and if it sometimes lead wrong, the true business of philosophy is to define when it may be trusted to as a safe guide, and what, on the other hand, are the circumstances which render its indications uncertain.

---

[1] In 1724.

The discourse of Bernoulli, just referred to, brought another new conclusion into the field, and began a controversy among the mathematicians of Europe, which lasted for many years. It was a new thing to see geometers contending about the truths of their own science, and opposing one demonstration to another. The spectacle must have given pain to the true philosopher, but may have afforded consolation to many who had looked with envy on the certainty and quiet prevailing in a region from which they found themselves excluded.

Descartes had estimated the force of a moving body, by the quantity of its motion, or by the product of its velocity into its mass. The mathematicians and philosophers who followed him did the same, and the product of these quantities was the measure of force universally adopted. No one, indeed, had ever thought of questioning the conformity of this measure to the phenomena of nature, when, in 1686, Leibnitz announced in the *Leipsic Journal* the *demonstration of a great error committed by Descartes and others, in estimating the force of moving bodies.* In this paper, the author endeavoured to show, that the force of a moving body is not proportional to its velocity simply, but to the square of its velocity, and he supported this new doctrine by very plausible reasoning. A body, he says, projected upward against gravity, with a double velocity, ascends to four times the height; with the triple velocity, to nine times the height, and so on; the height ascended to being always as the square of the velocity. But the height ascended to is the effect, and is the natural measure of the force, therefore the force of a moving body is as the square of its velocity. Such was the first reasoning of Leibnitz on this subject,—simple, and apparently conclusive; nor should it be forgotten that, during the long period to which the dispute was lengthened out, and notwithstanding the various shapes which it assumed, the reasonings on his side were nothing more than this original argument, changed in its form, or rendered more complex by the combination of new circumstances, so as to be more bewildering to the imagination, and more difficult either to apprehend or to refute.[1]

---

[1] To mere pressure, Leibnitz gave the name of *vis mortua,* and to the force of moving bodies the name

John Bernoulli was at first of a different opinion from his friend and master, but came at length to adopt the same, which, however, appears to have gone no farther till the discourse was submitted to the Academy of Sciences, as has been already mentioned. The mathematical world could not look with indifference on a question which seemed to affect the vitals of mechanical science, and soon separated into two parties, in the arrangement of which, however, the effects of national predilection might easily be discovered. Germany, Holland, and Italy, declared for the *vis viva;* England stood firm for the old doctrine; and France was divided between the two opinions. No controversy, perhaps, was ever carried on by more illustrious disputants; Maclaurin, Stirling, Desaguliers, Jurin, Clarke, Mairan, were all engaged on the one side, and on the opposite were Bernoulli, Herman, Poleni, S'Gravesende, Muschenbroek; and it was not till long after the period to which this part of the Dissertation is confined, that the debate could be said to be brought to a conclusion. That I may not, however, be obliged to break off a subject of which the parts are closely connected together, I shall take the liberty of transgressing the limits which the consideration of time would prescribe, and of now stating, as far as my plan admits of it, all that respects this celebrated controversy.

A singular circumstance may be remarked in the whole of the dispute. The two parties who adopted such different measures of force when any mechanical problem was proposed concerning the action of bodies, whether at rest or in motion, resolved it in the same manner, and arrived exactly at the same conclusions. It was therefore evident, that, however much their language and words were opposed, their ideas or opinions exactly agreed. In reality, the two parties were not at issue on the question; their positions, though seemingly opposite. were not contrary to one another; and after debating foı nearly thirty years, they found out this to be the truth. That the first men in the scientific world should have disputed so long with one another, without discovering that their opposition was only in words, and that this should have happened, not in any of the obscure and tortuous tracts through which the human mind must grope its way in anxiety and doubt, but in one of the clearest and straightest roads, where it used to be guided by the light of demonstration, is one of the most singular facts in the history of human knowledge.

The degree of acrimony and illiberality which were sometimes mixed in this con-

---

of *vis viva.* The former he admitted to be proportional to the simple power of the *virtual* velocity, and the second he held to be proportional to the square of the *actual* velocity.

troversy was not very creditable to the disputants, and proved how much more men take an interest in opinions as being their own, than as being simply in themselves either true or false. The dispute, as conducted by S'Gravesende and Clarke, took this turn, especially on the part of the latter, who, in the schools of theology having sharpened both his temper and his wit, accompanied his reasonings with an insolence and irritability peculiarly ill suited to a discussion about matter and motion. His paper on this subject, in the *Philosophical Transactions*,[1] contains many just and acute remarks, accompanied with the most unfair representation of the argument of his antagonists, as if the doctrine of the *vis viva* were a matter of as palpable absurdity as the denial of one of the axioms of geometry.[2] Now, the truth is, that the argument in favour of living forces is not at all liable to this reproach. One of the effects produced by a moving body is proportional to the square of the velocity, while another is proportional to the velocity simply; and, according to which of these ways the force itself is to be measured, may involve the propriety or impropriety of mathematical language, but cannot be charged with absurdity or contradiction. Absurdity, indeed, was a reproach that neither side had any right to cast on the other.

A dissertation of Mairan, on the force of moving bodies, in the *Memoires of the Academy of Sciences* for 1728, is one of those in which the common measure of force is most ably supported. Nevertheless, for a long time after this, the opinions on that subject in France continued still to be divided. In the list of the disputants we should hardly expect to find a lady included, if we did not know that the name of Madame du Chastellet, along with those of Hypatia and Agnesi, was honourably enrolled in the annals of mathematical learning. Her writings on this subject are full of ingenuity, though, from the fluctuation[3] of her opinions, it seems as if she had not yet entirely exchanged the caprice of fashion for the austerity of science. About the same time Voltaire engaged in the argument, and in a *Memoire,*[1] presented to the Academy of Sciences in 1741, contended that the dispute was entirely about words. His reasoning is on the whole sound, and the suffrage of one who united the character of a wit, a poet, and a philosopher, must be of great importance in a country where the despotism of fashion extends even to philosophical opinion.

---

[1] Vol. XXXV. (1728), p. 381. Hutton's *Abridgment*, Vol. VII, p. 219.

[2] In all the arguments for the *vis viva*, this learned metaphysician saw nothing but a conspiracy formed against the Newtonian philosophy. "An extraordinary instance," says he, "of the maintenance of the most palpable absurdity we have had in late years of very eminent mathematicians, Leibnitz, Bernoulli, Herman, Gravesende, who, in order to raise a dust of opposition against the Newtonian philosophy, some years back insisted with great eagerness on a principle which subverts all science, and which easily may be made appear, even to an ordinary capacity, to be contrary to the necessary and essential nature of things." This passage may serve as a proof of the spirit which prevailed among the philosophers of that time, making them ascribe such illiberal views to one another, and distorting so entirely both their own reasoning and those of their adversaries. The spirit awakened by the discovery of fluxions had not yet subsided.

[3] Mad. du Chastellet, in a *Dissertation on Fire*, published in 1740, took the side of Mairan, and bestowed great praise on his discourse on the force of moving bodies. Having, however, afterwards become a convert to the philosophy of Leibnitz, she espoused the cause of the *Vis Viva*, and wrote against Mairan. At

The controversy was now drawing to a conclusion,[2] and in effect may be said to have been terminated by the publication of D'Alembert's *Dynamique* in 1743. I am not certain, however, that all the disputants acquiesced in this decision, at least till some years later. Dr. Reid, in an essay *On Quantity*, in the *Philosophical Transactions* for 1748, has treated of this controversy, and remarked, that it had been dropt rather than concluded. In this I confess I differ from the learned author. The controversy seemed fairly ended, the arguments exhausted, and the conclusion established, that the propositions maintained by both sides were true, and were not opposed to one another. Though the mathematical sciences cannot boast of never having had any debates, they can say that those that have arisen have always been brought to a satisfactory termination.

The observations with which I am to conclude the present sketch, are not precisely the same with those of the French philosopher, though they rest nearly on the same foundation.

As the effects of moving bodies, or the changes they produce, may vary considerably with accidental circumstances, we must, in order to measure their force, have recourse to effects which are uniform, and not under the influence of variable causes. First, we may measure the force of one moving body by its effect upon another moving body; and here there is no room for dispute, nor any doubt that the forces of such bodies are as the quantities of matter multiplied into the simple power of the velocities, because

---

this time too she drew up a compend of the Leibnitian philosophy for the use of her son, which displays ingenuity and acuteness, and is certainly such a present as very few mothers have ever been in a condition to make to their children. Soon afterwards the same lady, having become a Newtonian, returned to her former opinion about the force of moving bodies, and in the end, gave to her countrymen an excellent translation of the *Principia* of Newton, with a commentary on a part of it, far superior to any other that has yet appeared.

[1] *Doutes sur la Mesure des Forces Motrices; Œuvres* de Voltaire, Tom. XXXIX. p. 91. 8vo. edit. 1785.

[2] Two very valuable papers that appeared at this late period of the dispute are found in the *Philosophical Transactions;* one by Desaguliers, in 1733, full of excellent remarks and valuable experiments; another by Jurin, in 1745, containing a very full state of the whole controversy.

the forces of bodies in which these products are equal, are well known, if opposed, to destroy one another. Thus one effect of moving bodies affords a measure of their force, which does not vary as the *square;* but as the *simple power* of the velocity.

There is also another condition of moving bodies which may be expected to afford a simple and general measure of their force. When a moving body it opposed by pressure, by a *vis mortua,* or a resistance like that of gravity, the quantity of such resistance required to extinguish the motion, and reduce the body to rest, must serve to measure the force of that body. It is a force which, by repeated impulses, has annihilated another, and these impulses, when properly collected into one sum, must evidently be equal to the force which they have extinguished. It happens, however, that there are two ways of computing the amount of these retarding forces, which lead to different results, both of them just, and neither of them to be assumed to the exclusion of the other.

Suppose the body, the force of which is to be measured, to be projected perpendicularly upward with any velocity, then, if we would compute the quantity of the force of gravity which is employed in reducing it to rest, we may either inquire into the retardation which that force produces during a given time, or while the body is moving over a given space. In other words, we may either inquire how long the motion will continue, or how far it will carry the body before it be entirely exhausted. If the length of the time that the uniform resistance must act before it reduce the body to rest be taken for the effect, and consequently for the measure of the force of the body, that force must be proportional to the velocity, for to this the time is confessedly proportional. If, on the other hand, the length of the line which the moving body describes, while subjected to this uniform resistance, be taken for the effect and the measure of the force, the force must be as the square of the velocity, because to that quantity the line in question is known to be proportional. Here, therefore, are two results, or two values of the same thing, the force of a moving body, which are quite different from one another; an inconsistency which evidently arises from this, that the thing denoted by the term *force,* is too vague and indefinite to be capable of measurement, unless some farther condition be annexed. This condition is no other than a specification of the work to be performed, or of the effect to be produced by the action of the moving body. Thus, when to the question concerning the force of the moving body, you add that it is to be employed in putting in motion another body, which is itself free to move, no doubt remains that the force is as the velocity multiplied into the quantity of matter. So also, if the force of the moving body is to be opposed by a resistance like that of gravity, the length of time that the motion may continue is one of its measurable effects, and that effect is, like the former, proportional to the velocity. There is a third effect to be considered, and one which always occurs in such an experiment as the last,—the height to which the moving body will ascend. This limitation gives to the force a definite character, and it is now measured by the square of the velocity. In fact, therefore, it is not a precise question to ask, What is the measure of the force of a moving body? You must, in addition, say, How is the moving body to be employed, or in which of its different capacities is it that you would measure its effect? In this state of the question there is no ambiguity, nor any answer to be given but one. Hence it was that the mathematicians and philosophers who differed so much about the general question of the force of moving bodies, never differed about the particular applications of that force. It was because the condition necessary for limiting the vagueness and ambiguity of the *data*, in all such cases, was fully supplied.

In the argument, therefore, so strenuously maintained on the force of moving bodies, both sides were partly in the right and both partly in the wrong. Each produced a measure of force which was just in certain circumstances, and thus far had truth on his side: but each argued that his was the only true measure, so that all others ought to be rejected; and here each of them was in error. Hence, also, it is not an accurate account of the controversy to say that it was about words merely; the disputants did indeed misunderstand one another, but their error lay in ascribing generality to propositions that were true only in particular cases, to which indeed the ambiguity and vagueness of the word *force* materially contributed. It does not appear, however, that any good would now accrue from changing the language of dynamics. If, as has been already said, to the question, How are we to measure the force of a moving body? be added the nature of the effect which is to be produced, all ambiguity will be avoided.

It is, I think, only farther necessary to observe, that, when the resistance opposed to the moving body is not uniform but variable, according to any law, it is not simply either the time or the space which is proportional to the velocity or to the square of the velocity, but functions of those quantities. These functions are obtained from the integration of certain fluxionary expressions, in which the measures above described are applied, the resistance being regarded as uniform for an infinitely small portion of the time or of the space.

Many years after the period I am now treating of, the controversy about the *vis* *viva* seemed to revive in England, on the occasion of an Essay on *Mechanical Force*, by the late Mr. Smeaton, an able engineer, who, to great practical skill, and much experience, added no inconsiderable knowledge of the mathematics.[1]

The reality of the *vis viva*, then, under certain conditions, is to be considered as a matter completely established. Another inquiry concerning the nature of this force, which also gave rise to considerable debate, was, whether, in the communication of motion, and in the various changes through which moving bodies pass, the quantity of the *vis viva* remains always the same? It had been observed, in the collision of elastic bodies, that the *vis viva*, or the sum made up by multiplying each body into the square of its velocity, and adding the products together, was the same after collision that it was before it, and it was concluded with some precipitation, by those who espoused the Leibnitian theory, that a similar result always took place in the real phenomena of nature. Other instances were cited; and it was observed, that a particular view of this principle which presented itself to Huygens, had enabled him to find the centre of oscillation of a compound pendulum, at a time when the state of mechanical science was scarcely prepared for so difficult an investigation. The proposition, however, is true only when all the changes are gradual, and rigorously subjected to the law of continuity. Thus, in the collision of bodies imperfectly elastic (a case which continually occurs in nature), the force which, during the recoil, accelerates the separation of the bodies, does not restore to them the whole velocity they had lost, and the *vis viva*, after the collision, is always less than it was before it. The cases in which the whole amount of the *vis viva* is rigorously preserved, may always be brought under the thirty-ninth proposition of the first book of the *Principia*, where the principle of this theory is placed on its true foundation.

So far as General Principles are concerned, the preceding are the chief mechanical improvements which belong to the period so honourably distinguished by the names of Newton and Leibnitz. The application of these principles to the solution of particular problems would afford materials for more ample discussion than suits the nature of a historical outline. Such problems as that of finding the centre of oscillation,—the nature of the catenarian curve,—the determination of the line of swiftest descent,—the retardation produced to motion in a medium that resists according to the square of the velocity, or indeed according to any function of it,—the determination of the elastic curve, or that into which an elastic spring forms itself when a force is applied to bend it,—all these were problems of the greatest interest, and were now resolved for the first time; the science of mechanics being sufficient, by means of the composition of forces, to find out the fluxionary or differential equations which expressed the nature of the gradual changes which in all these cases were produced, and the calculus being now sufficiently powerful to infer the properties of the finite from those of the infinitesimal quantities.

---

[1] Note E, at the end.

The doctrine of Hydrostatics was cultivated in England by Cotes. The properties of the atmosphere, or of elastic fluids, were also experimentally investigated; and the barometer, after the ingenuity of Pascal had proved that the mercury stood lower the higher up into the atmosphere the instrument was carried, was at length brought to be a measure of the height of mountains. Mariotte appears to have been the first who proposed this use of it, and who discovered that, while the height from the ground increases in arithmetical, the density of the atmosphere, and the column of mercury in the barometer, decrease in geometrical progression. Halley, who seems also to have come of himself to the same conclusion, proved its truth by strict geometrical reasoning, and showed, that logarithms are easily applicable on this principle to the problem of finding the height of mountains. This was in the year 1685. Newton two years afterwards gave a demonstration of the same, extended to the case when gravity is not constant, but varies as any power of the distance from a given centre.

To the assiduous observations and the indefatigable activity of Halley, the natural history of the atmosphere, of the ocean, and of magnetism, are all under the greatest obligations. For the purpose of inquiring into these objects, this ardent and philosophical observer relinquished the quiet of academical retirement, and, having gone to St. Helena, by a residence of a year in that island, not only made an addition to the catalogue of the stars, of 360 from the southern hemisphere, but returned with great acquisitions both of nautical and meteorological knowledge. His observations on evaporation were the foundation of two valuable papers on the origin of fountains; in which, for the first time, the sufficiency of the vapour taken up into the atmosphere, to maintain the perennial flow of springs and rivers, was established by undeniable evidence. The difficulty which men found in conceiving how a precarious and accidental supply like that of the rains, can sufficiently provide for a great and regular expenditure like that of the rivers, had given rise to those various opinions concerning the origin of fountains, which had hitherto divided the scientific world. A long residence on the summit of an insulated rock, in the midst of a vast ocean, visited twice every year by the vertical sun, would have afforded to an observer, less quick-sighted than Halley, an opportunity of seeing the work of evaporation carried on with such rapidity and copiousness as to be a subject of exact measurement. From this extreme case, he could infer the medium quantity, at least by approximation; and he proved that, in the Mediterranean, the humidity daily raised up by evaporation is three times as great as that which is discharged by all the rivers that flow into it. The origin of fountains was no longer questioned, and of the multitude of opinions on that subject, which had hitherto perplexed philosophers, all but one entirely disappeared.[1]

Beside the voyage to St. Helena, Halley made two others; the British government having been enlightened, and liberal enough to despise professional *etiquette*, where the interests of science were at stake, and to entrust to a Doctor of Laws the command of a ship of war, in which he traversed the Atlantic and Pacific Oceans in various directions, as far as the 53d degree of south latitude, and returned with a collection of facts and observations for the improvement of geography, meteorology, and navigation, far beyond that which any individual traveller or voyager had hitherto brought together.

The variation of the compass was long before this time known to exist, but its laws had never yet been ascertained. These Halley now determined from his own observations, combined with those of former navigators, in so far as to trace, on a nautical chart, the lines of the same variation over a great part both of the Atlantic and Pacific Oceans, affording to the navigator the ready means of correcting the errors which the deviation of the needle from the true meridian was calculated to produce. In his different traverses he had four times intersected the line of no variation, which seemed to divide the earth into two parts, the variations on the east side being towards the west, and on the west side towards the east. These lines being found to change their position in the course of time, the place assigned to the magnetical poles could not be permanent. Any theory, therefore, which could afford an explanation of their changes must necessarily be complex and difficult to be established. The attempt of Halley to give such an explanation, though extremely ingenious, was liable to great objections, and while it has shared the fate of most of the theories which have been laid down before the phenomena had been sufficiently explored, the general facts which he established have led to most of the improvements and discoveries which have since been made respecting the polarity of the needle.

---

[1] *Philosophical Transactions*, 1687, Vol. XVI. p. 366.

Besides the conclusion just mentioned, Dr Halley derived, from his observations, a very complete history of the winds which blow in the tropical regions, viz. the trade-wind, and the monsoons, together with many interesting facts, concerning the phenomena of the tides. The chart which contained an epitome of all these facts was published in 1701.

The above are only a part of the obligations which the sciences are under to the observations and reasonings of this ingenious and indefatigable inquirer. Halley was indeed one of the ablest and most accomplished men of his age. A scholar well versed in the learned languages, and a geometer profoundly skilled in the ancient analysis, he restored to their original elegance some of the precious fragments of that analysis, which time happily had not entirely defaced. He was well acquainted also with the algebraical and fluxionary calculus, and was both in theory and practice a profound and laborious astronomer. Finally, he was the friend of Newton, and often stimulated, with good effect, the tardy purposes of that great philosopher. Few men, therefore, of any period, have more claims than Halley on the gratitude of succeeding ages.

The invention of the thermometer has been already noticed, and the improvements made on that instrument about this period, laid the foundation of many future discoveries. The discovery of two fixed temperatures, each marked by the same expansion of the mercury in the thermometer, and the same condition of the fluid in which it is immersed, was made about this time. The differences of temperature were thus subjected to exact measurement; the phenomena of heat became, of course, known with more certainty and precision; and that substance or virtue, to which nothing is impenetrable, and which finds its way through the rarest and the densest bodies, apparently with the same facility,—which determines so many of our sensations, and of which the distribution so materially influences all the phenomena of animal and vegetable life, came now to be known, not indeed in its essence, but as to all the characters in which we are practically or experimentally concerned. The treatise on Fire, in Boerhaave's *Chemistry*, is a great advance beyond any thing on that subject hitherto known, and touches, notwithstanding many errors and imperfections, on most of the great truths, which time, experience, and ingenuity, have since brought into view.

It was in this period also, that electricity may be said first to have taken a scientific form. The power of amber to attract small bodies, after it has been rubbed, is said to have been known to Thales, and is certainly made mention of by Theophrastus. The observations of Gilbert, a physician of Colchester, in the end of the sixteenth century, though at the distance of two thousand years, made the first addition to the transient and superficial remarks of the Greek naturalist, and afford a pretty full enumeration of the bodies which can be rendered electrical by friction. The Academia del Cimento, Boyle, and Otto Guericke, followed in the same course; and the latter is the first who mentions the crackling noise and faint light which electricity sometimes produced. These, however, were hardly perceived, and it was by Dr Wall, as described in the *Philosophical Transactions*, that they were first distinctly observed.[1] By a singularly fortunate anticipation, he remarks of the light and crackling, that they seemed in some degree to represent thunder and lightning.

After the experiments of Hauksbee in 1709, by which the knowledge of this mysterious substance was considerably advanced, Wheeler and Gray, who had discovered that one body could communicate electricity to another without rubbing, being willing to try to what distance the electrical virtue might be thus conveyed, employed, for the purpose of forming the communication, a hempen rope, which they extended to a considerable length, supporting it from the sides, by threads which, in order to prevent the dissipation of the electricity, they thought it proper to make as slender as possible. They employed silk threads with that view, and found the experiment to succeed. Thinking that it would succeed still better, if the supports were made still more slender, they tried very fine metallic wire, and were surprised to find, that the hempen rope, thus supported, conveyed no electricity at all. It was, therefore, as being *silk,* and not as being *small,* that the threads had served to retain the electricity. This accident led to the great distinction of substances conducting, and not conducting electricity. An extensive field of inquiry was thus opened, a fortunate accident having supplied an *instantia crucis,* and enabled these experimenters to distinguish between what was essential and what was casual in the operation they had performed. The history of electricity, especially in its early stages, abounds with facts of this kind; and no man, who would study the nature of inductive science, and the rules for the interpretation of nature, can employ himself better than in tracing the progress of these discoveries. He will find abundant reason to admire the ingenuity as well as the industry of the inquirers, but he will often find accident come in very opportunely to the assistance of both. The experiments of Wheeler and Gray are described in the *Transactions* for 1729.

---

[1] Wall's paper is in the *Transactions* for 1708, Vol. XXVI. No. 314, p. 69.—Hauksbee on *Electrical Light*, in the same volume. See *Abridgment*, Vol. V. 408, 411.

SECTION III.

OPTICS.

THE invention of the telescope and the microscope, the discoveries made concerning the properties of light and the laws of vision, added to the facility of applying mathematical reasoning as an instrument of investigation, had long given a peculiar interest to optical researches. The experiments and inquiries of Newton on that subject began in 1666, and soon made a vast addition both to the extent and importance of the science. He was at that time little more than twenty-three years old; he had already made some of the greatest and most original discoveries in the pure mathematics; and the same young man, whom we have been admiring as the most profound and inventive of geometers, is to appear, almost at the same moment, as the most patient, faithful, and sagacious interpreter of nature. These characters, though certainly not opposed to one another, are not often combined; but to be combined in so high a degree, and in such early life, was hitherto without example.

In hopes of improving the telescope, by giving to the glasses a figure different from the spherical, he had begun to make experiments, and had procured a glass prism, in order, as he tells us, to try with it the *celebrated phenomena of colours.*[1] These trials led to the discovery of the different refrangibility of the rays of light, and are now too well known to stand in need of a particular description.

---

[1] *Phil. Trans.* Vol. VI. (1672), p. 3075. Also Hutton's *Abridgment*, Vol. I. p. 678. The account of the experiments is in a letter to Oldenburgh, dated February 1672; it is the first of Newton's works that was published. It is plain from what is said above, that the phenomena of the prismatic spectrum were not unknown at that time, however little they were understood, and however imperfectly observed.

Having admitted a beam of light into a dark chamber, through a hole in the window-shutter, and made it fall on a glass prism, so placed as to cast it on the opposite wall, he was delighted to observe the brilliant colouring of the sun's image, and not less surprised to observe its figure, which, instead of being circular, as he expected, was oblong in the direction perpendicular to the edges of the prism, so as to have the shape of a parallelogram, rounded at the two ends, and nearly five times as long as it was broad.

When he reflected on these appearances, he saw nothing that could explain the elongation of the image but the supposition that some of the rays of light, in passing through the prism, were more refracted than others, so that rays which were parallel when they fell on the prism, diverged from one another after refraction, the rays that differed in refrangibility differing also in colour. The *spectrum*, or solar image, would thus consist of a series of circular images, partly covering one another, and partly projecting one beyond another, from the red or least refrangible rays, in succession, to the orange, yellow, green, blue, indigo, and violet, the most refrangible of all.

It was not, however, till he tried every other hypothesis which suggested itself to his mind by the test of experiment, and proved its fallacy, that he adopted this as a true interpretation of the phenomena. Even after these rejections, his explanation had still to abide the sentence of an *experimentum crucis*.

Having admitted the light and applied a prism as before, he received the coloured spectrum on a board at the distance of about twelve feet from the first, and also pierced with a small hole. The coloured light which passed through this second hole was made to fall on a prism, and afterwards received on the opposite wall. It was then found that the rays which had been most refracted, or most bent from their course by the first prism, were most refracted also by the second, though no new colours were produced. "So," says he, "the true cause of the length of the image was detected to be no other than that light consists of rays differently refrangible, which, without any respect to a difference in their incidence, were, according to their degrees of refrangibility, transmitted towards divers parts of the wall."[1]

It was also observed, that when the rays which fell on the second prism were all of the same colour, the image formed by refraction was truly circular, and of the same colour with the incident light. This is one of the most conclusive and satisfactory of all the experiments.

---

[1] *Phil. Trans.* Vol. VI. (1672), No. 80. p. 3075.

When the sun's light is thus admitted first through one aperture, and then through another at some distance from the first, and is afterwards made to fall on a prism, as the rays come only from a part of the sun's disk, the spectrum has nearly the same length as before, but the breadth is greatly diminished; in consequence of which, the light at each point is purer, it is free from penumbra, and the confines of the different colours can be more accurately traced. It was in this way that Newton measured the extent of each colour, and taking the mean of a great number of measures, he assigned the following proportions, dividing the whole length of the spectrum, exclusive of its rounded terminations, into 360 equal parts; of these the

Red occupied -	45
Orange - -	27
Yellow - -	48
Green - -	60
Blue - -	60
Indigo - -	40
Violet - -	80

Between the divisions of the spectrum, thus made by the different colours, and the divisions of the monochord by the notes of music, Newton conceived that there was an analogy, and indeed an identity of ratios; but experience has since shown that this analogy was accidental, as the species occupied by the different colours do not divide the spectrum in the same ratio, when prisms of different kinds of glass are employed.

Such were the experiments by which Newton first " untwisted all the shining robe of day," and made known the texture of the magic garment which nature has so kindly spread over the surface of the visible world. From them it followed, that colours are not qualities which light derives from refraction or reflection, but are original and *connate* properties connected with the different degrees of refrangibility that belong to the different rays. The same colour is always joined to the same degree of refrangibility, and conversely, the same degree of refrangibility to the same colour.

Though the seven already enumerated are primary and simple colours, any of them may also be produced by a mixture of others. A mixture of yellow and blue, for instance, makes green; of red and yellow orange; and, in general, if two colours, which are not very far asunder in the natural series, be mixed together, they compound the colour that is in the middle between them.

But the most surprising composition of all, Newton observes, is that of whiteness; which is not produced by one sort of rays, but by the mixture of all the colours in a certain proportion, namely, in that proportion which they have in the solar spectrum. This fact may be said to be made out both by analysis and composition. The white light of the sun can be separated, as we have just seen, into the seven simple colours; and if these colours be united again they form white. Should any of them have been wanting, or not in its due proportion, the white produced is defective.

It appeared, too, that natural bodies, of whatever colour, if viewed by simple and homogeneous light, are seen of the colour of that light and of no other. Newton tried this very satisfactory experiment on bodies of all colours, and found it to hold uniformly; the light was never changed by the colour of the body that reflected it.

Newton, thus furnished with so many new and accurate notions concerning the nature and production of colour, proceeded to apply them to the explanation of phenomena. The subject which naturally offered itself the first to this analysis was the rainbow, which, by the grandeur and simplicity of its figure, added to the brilliancy of its colours, in every age has equally attracted the attention of the peasant and of the philosopher. That two refractions and one reflection were at least a part of the machinery which nature employed in the construction of this splendid arch, had been known from the time of Antonio de Dominis;[1] and the manner in which the arched figure is produced had been shown by Descartes; so that it only remained to explain the nature of the colour and its distribution. As the colours were the same with those exhibited by the prism, and succeeded in the same order, it could hardly be doubted that the cause was the same. Newton showed the truth of his principles by calculating the extent of the arch, the breadth of the coloured bow, the position of the secondary bow, its distance from the primary, and by explaining the inversion of the colours.[2] There is not, perhaps, in science any happier application of theory, or any in which the mind rests with fuller confidence.

Other meteoric appearances seemed to be capable of similar explanations, but the phenomena being no where so regular or so readily subjected to measurement as those of the rainbow, the theory cannot be brought to so severe a test, nor the evidence rendered so satisfactory.

---

[1] Note F, at the end.

[2] *Optics*, Book I. prop. 9.

But a more difficult task remained,—to explain the permanent colour of natural bodies. Here, however, as it cannot be doubted that all colour comes from the rays of light, so we must conclude that one body is red and another violet, because the one is disposed to reflect the red or least refrangible rays, and the other to reflect the violet or the most refrangible. Every body manifests its disposition to reflect the light of its own peculiar colour, by this, that if you cast on it pure light, first of its own colour, and then of any other, it will reflect the first much more copiously than the second. If cinnabar, for example, and ultra-marine blue be both exposed to the same red homogeneous light, they will both appear red; but the cinnabar strongly luminous and resplendent, and the ultra-marine of a faint obscure red. If the homogeneal light thrown on them be blue, the converse of the above will take place.

Transparent bodies, particularly fluids, often transmit light of one colour and reflect light of another. Halley told Newton, that, being deep under the surface of the sea in a diving-bell, in a clear sunshine day, the upper side of his hand, on which the sun shone darkly through the water, and through a small glass window in the diving-bell, appeared of a red colour, like a damask rose, while the water below, and the under part of his hand, looked green.[1]

But, in explaining the permanent colour of bodies, this difficulty always presents itself,—Suppose that a body reflects red or green light, what is it that decomposes the light, and separates the red or the green from the rest? Refraction is the only means of decomposing light, and separating the rays of one degree of refrangibility and of one colour, from those of another. This appears to have been what led Newton to study the colours produced by light passing through thin plates of any transparent substance. The appearances are very remarkable, and had already attracted the attention, both of Boyle and of Hook, but the facts observed by them remained insulated in their hands, and unconnected with other optical phenomena.

It probably had been often remarked, that when two transparent bodies, such as glass, of which the surfaces were convex in a certain degree, were pressed together, a black spot was formed at the contact of the two, which was surrounded with coloured rings, more or less regular, according to the form of the surfaces. In order to analyse a phenomenon that seemed in itself not a little curious, Newton proposed to make the experiment with surfaces of a regular curvature, such as was capable of being measured. He took two object glasses, one a plano-convex for a fourteen feet telescope, the other a double convex for one of about fifty feet, and upon this last he laid the other with its plane side downwards, pressing them gently together. At their contact in the centre was a pellucid spot, through which the light passed without suffering any reflection. Round this spot was a coloured circle or ring, exhibiting blue, white, yellow, and red. This was succeeded by a pellucid or dark ring, then a coloured ring of violet, blue, green, yellow, and red, all copious and vivid except the green. The third coloured ring consisted of purple, blue, green, yellow, and red. The fourth consisted of green and red; those that succeeded became gradually more dilute and ended in whiteness. It was possible to count as far as seven.

---

[1] *Optics*, p. 115. Horseley's edit.

The colours of these rings were so marked by peculiarities in shade and vivacity, that Newton considered them as belonging to different orders; so that an eye accustomed to examine them, on any particular colour of a natural object being pointed out, would be able to determine to what order in this series it belonged.

Thus we have a system of rings or zones surrounding a dark central spot, and themselves alternately dark and coloured, that is, alternately transmitting the light and reflecting it. It is evident that the thickness of the plates of air interposed between the glasses, at each of those rings, must be a very material element in the arrangement of this system. Newton, therefore, undertook to compute their thickness. Having carefully measured the diameters of the first six coloured rings, at the most lucid part of each, he found their squares to be as the progression of odd numbers 1, 3, 5, 7, &c. The squares of the distances from the centre of the dark spot to each of these circumferences, were, therefore, in the same ratio, and consequently the thickness of the plates of air, or the intervals between the glasses, were as the numbers 1, 3, 5, 7, &c.

When the diameters of the dark or pellucid rings which separated the coloured rings were measured, their squares were found to be as the even numbers 0, 2, 4, 6, and, therefore, the thickness of the plates through which the light was wholly transmitted were as the same numbers. A great many repeated measurements assured the accuracy of these determinations.

As the curvature of the convex glass on which the flat surface of the plano-convex rested was known, and as the diameters of the rings were measured in inches, it was easy to compute the thickness of the plates of air, which corresponded to the different rings.

An inch being divided into 178000 parts, the distance of the lenses for the first series, or for the luminous rings, was $\frac{1}{178000}$, $\frac{3}{178000}$, $\frac{5}{178000}$, &c.

For the second series $\frac{2}{178000}$, $\frac{4}{178000}$, &c.

When the rings were examined by looking through the lenses in the opposite direction, the central spot appeared white, and, in other rings, red was opposite to blue, yellow to violet, and green to a compound of red and violet; the colours formed by the transmitted and the reflected light being, what is now called, complementary, or nearly so, of one another; that is, such as when mixed produce white.

When the fluid between the glasses was different from air, as when it was water, the succession of rings was the same; the only difference was, that the rings themselves were narrower.

When experiments on thin plates were made in such a way that the plate was of a denser body than the surrounding medium, as in the case of soap-bubbles, the same phenomena were observed to take place. These phenomena Newton also examined with his accustomed accuracy, and even bestowed particular care on having the soap-bubbles as perfect and durable as their frail structure would admit. In the eye of philosophy no toy is despicable, and no occupation frivolous, that can assist in the discovery of truth.

To the different degrees of tenuity, then, in transparent substances, there seemed to be attached the powers of separating particular colours from the mass of light, and of rendering them visible sometimes by reflection, and, in other cases, by transmission. As there is reason to think, then, that the minute parts, the mere particles of all bodies, even the most opaque, are transparent, they may very well be conceived to act on light after the manner of the thin plates, and to produce each, according to its thickness and density, its appropriate colour, which, therefore, becomes the colour of the surface. Thus the colours in which the bodies round us appear everywhere arrayed, are reducible to the action of the parts which constitute their surfaces on the refined and active fluid which pervades, adorns, and enlightens the world.

But the same experiments led to some new and unexpected conclusions, that seemed to reach the very essence of the fluid of which we now speak. It was impossible to observe, without wonder, the rings alternately luminous and dark that were formed between the two plates of glass in the preceding experiments, and determined to be what they were by the different thickness of the air between the plates, and having to that thickness the relations formerly expressed. A plate of which the thickness was equal to a certain quantity multiplied by an odd number, gave always a circle of the one kind; but if the thickness of the plate was equal to the same quantity multiplied by an even number, the circle was of another kind, the light, in the first case, being reflected, in the second transmitted. Light penetrating a thin transparent plate, of which the thickness was m, $3m$, $5m$, &c. was decomposed and reflected; the same light penetrating the same plate, but of the thickness 0, $2m$, $4m$, was transmitted, though, in a certain degree, also decomposed. The same light, therefore, was transmitted or reflected, according as the second surface of the plate of air through which it passed was distant from the first by the intervals 0, 2, $4m$, or m, $3m$, $5m$; so that it becomes necessary to suppose the same ray to be successively disposed to be transmitted and to be reflected at points of space separated from one another by the same interval m. This constitutes what Newton called *Fits of easy transmission and easy reflection*, and forms one of the most singular parts of his optical discoveries. It is so unlike any thing which analogy teaches us to expect, that it has often been viewed with a degree of incredulity, and regarded as at best but a conjecture introduced to account for certain optical phenomena. This, however, is by no means a just conclusion, for it is, in reality, a necessary inference from appearances accurately observed, and is no less entitled to be considered as a fact than those appearances themselves. The difficulty of assigning a cause for such extraordinary alternations cannot be denied, but does not entitle us to doubt the truth of a conclusion fairly deduced from experiment. The principle has been confirmed by phenomena that were unknown to Newton himself, and possesses this great and unequivocal character of philosophic truth, that it has served to explain appearances which were not observed till long after the time when it first became known.

We cannot follow the researches of Newton' into what regards the colours of thick plates, and of bodies in general. We must not, however, pass over his explanation of refraction, which is among the happiest to be met with in any part of science, and has the merit of connecting the principles of optics with those of dynamics.

The theory from which the explanation we speak of is deduced is, that light is an emanation of particles, moving in straight lines with incredible velocity, and attracted by the particles of transparent bodies. When, therefore, light falls obliquely on the surface of such a body, its motion may be resolved into two, one parallel to that surface, and the other perpendicular to it. Of these, the first is not affected by the attraction of the body, which is perpendicular to its own surface; and, therefore, it remains the same in the refracted that it was in the incident ray. But the velocity perpendicular to the surface is increased by the attraction of the body, and, according to the principles of dynamics (the 39th, Book I. *Princip.*), whatever be the quantity of this velocity, its square, on entering the same transparent body, will always be augmented by the same quantity. But it is easy to demonstrate that, if there be two right-angled triangles, with a side in the one equal to a side in the other, the hypothenuse of the first being given, and the squares of their remaining sides differing by a given space, the sines of the angles opposite to the equal sides must have a given ratio to one another.[1] This amounts to the same with saying, that, in the case before us, the sine of the angle of incidence is to the sine of the angle of refraction in a given ratio. The explanation of the law of refraction thus given is so highly satisfactory, that it affords a strong argument in favour of the system which considers light as an emanation of particles from luminous bodies, rather than the vibrations of an elastic fluid. It is true that Huygens deduced from this last hypothesis an explanation of the law of refraction, on which considerable praise was bestowed in the former part of this Dissertation. It is undoubtedly very ingenious, but does not rest on the same solid and undoubted principles of dynamics with the preceding, nor does it leave the mind so completely satisfied. Newton, in his *Principia*, has deduced another demonstration of the same optical proposition from the theory of central forces.[2]

The different refrangibility of the rays of light forms no exception to the reasoning above. The rays of each particular colour have their own particular ratio subsisting between the sines of incidence and refraction, or in each, the square that is added to the square of the perpendicular velocity has its own value, which continues the same while the transparent medium is the same.

Light, in consequence of these views, became, in the hands of Newton, the means of making important discoveries concerning the internal and chemical constitution of bodies. The square that is added to that of the perpendicular velocity of light in consequence of the attractive force of the transparent substance, is properly the measure of the quantity of that attraction, and is the same with the difference of the squares of the velocities of the incident and the refracted light. This is readily deduced, therefore, from the ratio of the angle of incidence to that of refraction; and when this is done for different substances, it is found, that the above measure of the refracting power of transparent bodies is nearly proportional to their density, with the exception of those which contain much inflammable matter in their composition, or sulphur, as it was then called, which is always accompanied with an increase of refracting power.[1]

---

[1] *Optics*, Book II. Part iii. prop. 10.

[2] *Prin. Math.* Lib. I. prop. 94. Also *Optics*, Book I. prop. 6.

Thus, the refracting power ascertained as above, when divided by the density, gives quotients not very different from one another, till we come to the inflammable bodies, where a great increase immediately takes place. In air, for instance, the quotient is 5208, in rock-crystal 5450, and the same nearly in common glass But in spirit of wine, oil, amber, the same quotients are 10121, 12607, 13654. Newton found in the diamond, that this quotient is still greater than any of the preceding, being 14556.[2] Hence he conjectured, what has since been so fully verified by experiment, that the diamond, at least in part, is an inflammable body. Observing, also, that the refracting power of water is great for its density, the quotient, expounding it, as above, being 7845, he concluded, that an inflammable substance enters into the composition of that fluid,—a conclusion which has been confirmed by one of the most certain but most unexpected results of chemical analysis. The views thus suggested by Newton have been successfully pursued by future inquirers, and the action of bodies on light is now regarded as one of the means of examining into their internal constitution.

I should have before remarked, that the alternate disposition to be easily reflected and easily transmitted, serves to explain the fact, that all transparent substances reflect a portion of the incident light. The reflection of light from the surfaces of opaque bodies, and from the anterior surfaces of transparent bodies, appears to be produced by a repulsive force exerted by those surfaces at a determinate but very small distance, in consequence of which there is stretched out over them an elastic web through which the particles of light, notwithstanding their incredible velocity, are not always able to penetrate.[3] In the case of a transparent body, the light which, when it arrives at this outwork, as it may be called, is in a *fit* of easy reflection, obeys of course the repulsive force, and is reflected back again. The particles, on the other hand, which are in the state which disposes them to be transmitted, overcome the repulsive force, and, entering into the interior of the transparent body, are subjected to the action of its attractive force, and obey the law of refraction already explained. If these rays, however, reach the second surface of the transparent body (that body being supposed denser than the medium surrounding it), in a direction having a certain obliquity to that surface, the attraction will not suffer the rays to emerge into the rarer medium, but will force them to return back into the transparent body. Thus the reflection of light at the second surface of a transparent body is produced, not by the repulsion of the medium in which it was about to enter, but by the attraction of that which it was preparing to leave.

---

[1] Newton's *Optics*, Ibid.

[2] Ibid.

[3] A velocity that enables light to pass from the sun to the earth in 8′ 13″, as is deduced from the eclipses of Jupiter's satellites.

The first account of the experiments from which all these conclusions were deduced, was given in the *Philosophical Transactions* for 1672, and the admiration excited by their brilliancy and their novelty may easily be imagined. Among the men of science, the most enlightened were the most enthusiastic in their praise. Huygens, writing to one of his friends, says of them, and of the truths they were the means of making known, "*Quorum respectu omnia huc usque edita jejunia sunt et prorsus puerilia.*" Such were the sentiments of the person who, of all men living, was the best able to judge and had the best right to be fastidious in what related to optical experiments and discoveries. But all were not equally candid with the Dutch philosopher; and though the discovery now communicated had every thing to recommend it which can arise from what is great, new, and singular; though it was not a theory or a system of opinions, but the generalization of facts made known by experiments; and though it was brought forward in the most simple and unpretending form, a host of enemies appeared, each eager to obtain the unfortunate pre-eminence of being the first to attack conclusions which the unanimous voice of posterity was to confirm. In this contention, the envy and activity of Hook did not fail to give him the advantage, and he communicated his objections to Newton's conclusions concerning the refrangibility of light in less than a month after they had been read in the Royal Society. He admitted the accuracy of the experiments themselves, but denied that the cause of the colour is any quality residing permanently in the rays of light, any more than that the sounds emitted from the pipes of an organ exist originally in the air. An imaginary analogy between sound and light seems to have been the basis of all his optical theories. He conceived that colour is nothing but the disturbance of light by pulses propagated through it; that blackness proceeds from the scarcity, whiteness from the plenty, of undisturbed light; and that the prism acts by exciting different pulses in this fluid, which pulses give rise to the sensations of colour. This obscure and unintelligible theory (if we may honour what is unintelligible with the name of a theory) he accompanied with a multitude of captious objections to the reasonings of Newton, whom he was not ashamed to charge with borrowing from him without acknowledgment. To all this Newton replied, with the solidity, calmness, and modesty, which became the understanding and the temper of a true philosopher.

The new theory of colours was quickly assailed by several other writers, who seem all to have had a better apology than Hooke for the errors into which they fell. Among them one of the first was Father Pardies, who wrote against the experiments, and what he was pleased to call the hypothesis, of Newton. A satisfactory and calm reply convinced him of his mistake, which he had the candour very readily to acknowledge. A countryman of his, Mariotte, was more difficult to be reconciled, and, though very conversant with experiment, appears never to have succeeded in repeating the experiments of Newton. Desaguliers, at the request of the latter, repeated the experiments doubted of before the Royal Society, where Monmort, a countryman and a friend of Mariotte, was present.[1]

MM. Linus and Lucas, both of Leige, objected to Newton's experiments as inaccurate; the first, because, on attempting to repeat them, he had not obtained the same results; and the second, because he had not been able to perceive that a red object and a blue required the focal distance to be different when they were viewed through a telescope. Newton replied with great patience and good temper to both.

The series was closed, in 1727, by the work of an Italian author, Rizetti, who, in like manner, called in question the accuracy of experiments which he himself had not been able to repeat. Newton was now no more, but Desaguliers, in consequence of Rizetti's doubts, instituted a series of experiments which seemed to set the matter entirely at rest. These experiments are described in the *Philosophical Transactions* for 1728.

An inference which Newton had immediately drawn from the discoveries above described was, that the great source of imperfection in the refracting telescope was the different refrangibility of the rays of light, and that there were stronger reasons than either Mersenne or Gregory had suspected, for looking to reflection for the improvement of optical instruments. It was evident, from the different refrangibility of light, that the rays coming from the same point of an object, when decomposed by the refraction of a lens, must converge to different foci; the red rays, for example, to a point more distant from the lens, and the violet to one nearer by about a fifty-fourth part of the focal distance. Hence it was not merely from the aberration of the rays caused by the spherical figure of the lens that the imperfection of the images formed by refraction arose, but from the very nature of refraction itself. It was evident, at the same time, that in a combination of lenses with opposite figures, one convex, for instance, and another concave, there was a tendency of the two contrary dispersions to correct one another. But it appeared to Newton, on examining different refracting substances, that the dispersion of the coloured rays never could be corrected except when the refraction itself was entirely destroyed, for he thought he had discovered that the quantity of the refraction and of the dispersion in different substances bore always the same proportion to one another. This is one of the few instances in which his conclusions have not been confirmed by subsequent experiment; and it will, accordingly, fall under discussion in another part of this discourse.

---

[1] Montucla, Tom. II.

Having taken the resolution of constructing a reflecting telescope, he set about doing so with his own hands. There was, indeed, at that time, no other means by which such a work could be accomplished; the art of the ordinary glass-grinder not being sufficient to give to metallic specula the polish which was required. It was on this account that Gregory had entirely failed in realizing his very ingenious optical invention.

Newton, however, himself possessed excellent hands for mechanical operations, and could use them to better purpose than is common with men so much immersed in deep and abstract speculation. It appears, indeed, that mechanical invention was one of the powers of his mind which began to unfold itself at a very early period. In some letters subjoined to a Memoir drawn up after his death by his nephew Conduit, it is said, that, when a boy, Newton used to amuse himself with constructing machines, mills, &c. on a small scale, in which he displayed great ingenuity; and it is probable that he then acquired that use of his hands which is so difficult to be learned at a later period. To this, probably, we owe the neatness and ingenuity with which the optical experiments above referred to were contrived and executed,—experiments of so difficult a nature, that any error in the manipulation would easily defeat the effect, and appears actually to have done so with many of those who objected to his experiments.[1]

He succeeded perfectly in the construction of his telescope, and his first communication with Oldenburg, and the first reference to his optical experiments, is connected with the construction of this instrument, and mentioned in a letter dated the 11th January 1672. He had then been proposed as a member of the Royal Society by the Bishop of Sarum, and he says, "If the honour of being a member of the Society shall be conferred on me, I shall endeavour to testify my gratitude by communicating what my poor and solitary endeavours can effect toward the promoting its philosophical designs."[2] Such was the modesty of the man who was to effect a greater revolution in the state of our knowledge of nature than any individual had yet done, and greater, perhaps, than any individual is ever destined to bring about. Success, however, never altered the temper in which he began his researches.

Newton, after considering the reflection and refraction of light, proceeded, in the third and last Book of his *Optics*, to treat of its *inflexion*, a subject which, as has been remarked in the former part of this discourse, was first treated of by Grimaldi. Newton having admitted a ray of light through a hole in a window-shutter into a dark chamber, made it pass by the edge of a knife, or, in some experiments, between the edges of two knives, fixed parallel, and very near to one another; and, by receiving the light on a sheet of paper at different distances behind the knives, he observed the coloured fringes which had been described by the Italian optician, and on examination, found, that the rays had been acted on in passing the knife edges both by repulsive and attractive forces, and had begun to be so acted on in a sensible degree when they were yet distant by $\frac{1}{800}$ of an inch of the edges of the knives. His experiments, however, on this subject were interrupted, as he informs us, and do not appear to have been afterwards resumed. They enabled him, however, to draw this conclusion, that the path of the ray in passing by the knife edge was bent in opposite directions, so as to form a serpentine line, convex and concave toward the knife, according to the repulsive or attractive forces which acted at different distances; that it was also reasonable to conclude, that the phenomena of the refraction, reflection, and inflexion of light were all produced by the same force variously modified, and that they did not arise from the actual contact or collision of the particles of light with the particles of bodies.

---

[1] The *Memoir* of Conduit was sent to Fontenelle when he was preparing the *Eloge* on Newton, but he seems to have paid little attention to it, and has passed over the early part of his life with the remark, that one may apply to him what Lucan says of the Nile, that it has not been "permitted to mortals to see that river in a feeble state." If the letters above referred to had formed a part of this communication, I think the Secretary of the Academy would have sacrificed a fine comparison to an instructive fact. In other respects Conduit's *Memoir* did not convey much information that could be of use. His instructions to Fontenelle are curious enough; he bids him be sure to state, that Leibnitz had borrowed the Differential Calculus from the Method of Fluxions. He conjured him in another place not to omit to mention, that Queen Caroline used to delight much in the conversation of Newton, and nothing could do more honour to Newton than the commendation of a Queen, the Minerva of her age. Fontenelle was too much a philosopher, and a man of the world (and had himself approached too near to the persons of princes), to be of Mr Conduit's opinion, or to think that the approbation of the most illustrious princess could add dignity to the man who had made the three greatest discoveries yet known, and in whose hands the sciences of Geometry, Optics, and Astronomy, had all taken new forms. If he had been called to write the *Eloge* of the Queen of England, he would, no doubt, have remarked her relish for the conversation of Newton.

On the whole, the *Eloge* on Newton has great merit, and, to be the work of one who was at bottom a Cartesian, is a singular example of candour and impartiality.

[2] Birch's *History of the Royal Society*, Vol. III. p. 3.

The Third Book of the *Optics* concludes with those celebrated *Queries* which carry the mind so far beyond the bounds of ordinary speculation, though still with the support and under the direction either of direct experiment or close analogy. They are a collection of propositions relative chiefly to the nature of the mutual action of light and of bodies on one another, such as appeared to the author highly probable, yet wanting such complete evidence as might entitle them to be admitted as principles established. Such enlarged and comprehensive views, so many new and bold conceptions, were never before combined with the sobriety and caution of philosophical induction. The anticipation of future discoveries, the assemblage of so many facts from the most distant regions of human research, all brought to bear on the same points, and to elucidate the same questions, are never to be sufficiently admired. At the moment when they appeared, they must have produced a wonderful sensation in the philosophic world, unless, indeed, they advanced too far before the age, and contained too much which the comment of time was yet required to elucidate.

It is in the *Queries* that we meet with the ideas of this philosopher concerning the *Elastic Ether*, which he conceived to be the means of conveying the action of bodies from one part of the universe to another, and to which the phenomena of light, of heat, of gravitation, are to be ascribed. Here we have his conclusions concerning that polarity or peculiar virtue residing in the opposite sides of the rays of light, which he deduced from the enigmatical phenomena of doubly refracting crystals. Here, also, the first step is made toward the doctrine of elective attractions or of chemical affinity, and to the notion, that the phenomena of chemistry, as well as of cohesion, depend on the alternate attractions and repulsions existing between the particles of bodies at different distances. The comparison of the gradual transition from repulsion to attraction at those distances, with the positive and negative quantities in algebra, was first suggested here, and is the same idea which the ingenuity of Boscovich afterwards expanded into such a beautiful and complete system. Others who have attempted such flights had ended in mere fiction and romance; it is only for such men as Bacon or Newton to soar beyond the region of poetical fiction, still keeping sight of probability, and alighting again safe on the *terra firma* of philosophic truth.[1]

SECTION IV.

ASTRONOMY.

THE time was now come when the world was to be enlightened by a new science, arising out of the comparison of the phenomena of motion as observed in the heavens, with the laws of motion as known on the earth. Physical astronomy was the result of this comparison, a science embracing greater objects, and destined for a higher flight than any other branch of natural knowledge. It is unnecessary to observe, that it was by Newton that the comparison just referred to was instituted, and the riches of the new science unfolded to mankind.

This young philosopher, already signalized by great discoveries, had scarcely reached the age of twenty-four, when a great public calamity forced him into the situation where the first step in the new science is said to have been suggested; and that, by some of those common appearances in which an ordinary man sees nothing to draw his attention, nor even the man of genius, except at those moments of inspiration when the mind sees farthest into the intellectual world. In 1666, the plague forced him to retire from Cambridge into the country; and, as he sat one day alone, in a garden, musing on the nature of the mysterious force by which the phenomena at the earth's surface are so much regulated, he observed the apples falling spontaneously from the trees, and the thought occurred to him, since gravity is a tendency not confined to bodies on the very surface of the earth, but since it reaches to the tops of trees, to the tops of the highest buildings, nay, to the summits of the most lofty mountains, without its intensity or direction suffering any sensible change, Why may it not reach to a much greater distance, and even to the moon itself? And, if so, may not the moon be retained in her orbit by gravity, and forced to describe a curve like a projectile at the surface of the earth?[1]

---

[1] The optical works of Newton are not often to be found all brought together into one body. The first part of them consists of the papers in the *Philosophical Transactions*, which gave the earliest account of his discoveries, and which have been already referred to. They are in the form of Letters to Oldenburg, the Secretary of the Society, as are also the answers, to Hooke, and the others who objected to these discoveries; the whole forming a most interesting and valuable series, which Dr. Horsely has published in the fourth volume of his edition of Newton's works, under the title of *Letters relating to the Theory of Light and Colours*. The next work, in point of time, consists of the *Lectiones Opticæ*, or the optical lectures which the author delivered at Cambridge. The *Optics*, in three books, is the last and most complete, containing all the reasoning concerning optical phenomena above referred to. The first edition was in 1704, the second, with additions, in 1717. *Newtoni Opera*, Tom. IV. Horsely's edition.

Here another consideration very naturally occurred. Though gravity be not sensibly weakened at the small distances from the surface to which our experiments extend, it may be weakened at greater distances, and at the moon may be greatly diminished. To estimate the quantity of this diminution Newton appears to have reasoned thus: If the moon be retained in her orbit by her gravitation to the earth, it is probable that the planets are, in like manner, carried round the sun by a power of the same kind with gravity, directed to the centre of that luminary. He proceeded, therefore, to inquire by what law the tendency, or gravitation of the planets to the sun must diminish, in order that, describing, as they do, orbits nearly circular round the sun, their times of revolution and their distances may have the relation to one another which they are known to have from observation, or from the third law of Kepler.

This was an investigation which, to most even of the philosophers and mathematicians of that age, would have proved an insurmountable obstacle to their farther progress; but Newton was too familiar with the geometry of evanescent or infinitely small quantities, not to discover very soon, that the law now referred to would require the force of gravity to diminish exactly as the square of the distance increased. The moon, therefore, being distant from the earth about sixty semidiameters of the earth, the force of gravity at that distance must be reduced to the 3600th part of what it is at the earth's surface. Was the deflection of the moon then from the tangent of her orbit, in a second of time, just the 3600th part of the distance which a heavy body falls in a second at the surface of the earth? This was a question that could be precisely answered, supposing the moon's distance known not merely in semidiameters of the earth but in feet, and her angular velocity, or the time of her revolution in her orbit, to be also known.

In this calculation, however, being at a distance from books, he took the common estimation of the earth's circumference that was in use before the measurement of Norwood, or of the French Academicians, according to which, a degree is held equal to 60 English miles. This being in reality a very erroneous supposition, the result of the calculation did not represent the force as adequate to the supposed effect: whence Newton concluded that some other cause than gravity must act on the moon, and on that account he laid aside, for the time, all farther speculation on the subject. It was in the true spirit of philosophy that he so readily gave up an hypothesis, in which he could not but feel some interest, the moment he found it at variance with observation. He was sensible that nothing but the exact coincidence of the things compared could establish the conclusion he meant to deduce, or authorize him to proceed with the superstructure, for which it was to serve as the foundation.

---

[1] Pemberton's *View of Newton's Philosophy*, Pref.

It appears, that it was not till some years after this, that his attention was called to the same subject, by a letter from Dr Hooke, proposing as a question, To determine the line in which a body let fall from a height descends to the ground, taking into consideration the motion of the earth on its axis. This induced him to resume the subject of the moon's motion; and the measure of a degree by Norwood having now furnished more exact data, he found that his calculation gave the precise quantity for the moon's momentary deflection from the tangent of her orbit, which was deduced from astronomical observation. The moon, therefore, has a tendency to descend toward the earth from the same cause that a stone at its surface has; and if the descent of the stone in a second be diminished in the ratio of 1 to 3600, it will give the quantity by which the moon descends in a second, below the tangent to her orbit, and thus is obtained an experimental proof of the fact, that gravity decreases as the square of the distance increases. He had already found that the times of the planetary revolutions, supposing their orbits to be circular, led to the same conclusion; and he now proceeded, with a view to the solution of Hooke's problem, to inquire what their orbits must be, supposing the centripetal force to be inversely as the square of the distance, and the initial or projectile force to be any whatsoever. On this subject Pemberton says, he composed (as he calls it) a dozen propositions, which probably were the same with those in the beginning of the *Principia*,—such as the description of equal areas in equal times, about the centre of force, and the ellipticity of the orbits described under the influence of a centripetal force that varied inversely as the square of the distances.

What seems very difficult to be explained is, that after having made trial of his strength, and of the power of the instruments of investigation which he was now in possession of, and had entered by means of them on the noblest and most magnificent field of investigation that was ever yet opened to any of the human race, he again desisted from the pursuit, so that it was not till several years afterwards that the conversation of Dr Halley, who made him a visit at Cambridge, induced him to resume and extend his researches.

He then found, that the three great facts in astronomy, which form the laws of Kepler, gave the most complete evidence to the system of gravitation. The *first* of them, the proportionality of the areas described by the radius vector to the times in which they are described, is the peculiar character of the motions produced by an original impulse impressed on a body, combined with a centripetal force continually urging it to a given centre. The *second* law, that the planets describe ellipses, having the sun in one of the foci, common to them all, coincides with this proposition, that a body under the influence of a centripetal force, varying as the square of the distance inversely, and having any projectile force whatever originally impressed on it, must describe a conic section having one focus in the centre of force, which section, if the projectile force does not exceed a certain limit, will become an ellipse. The *third* law, that the squares of the periodic times are as the cubes of the distances, is a property which belongs to the bodies describing elliptic orbits under the conditions just stated. Thus the three great truths to which the astronomy of the planets had been reduced by Kepler, were all explained in the most satisfactory manner, by the supposition that the planets gravitate to the sun with a force which varies in the inverse ratio of the square of the distances. It added much to this evidence, that the observations of Cassini had proved the same laws to prevail among the satellites of Jupiter.

But did the principle which appeared thus to unite the great bodies of the universe act only on those bodies? Did it reside merely in their centres, or was it a force common to all the particles of matter? Was it a fact that every particle of matter had a tendency to unite with every other? Or was that tendency directed only to particular centres? It could hardly be doubted that the tendency was common to all the particles of matter. The centres of the great bodies had no properties as mathematical points, they had none but what they derived from the material particles distributed around them. But the question admitted of being brought to a better test than that of such general reasoning as the preceding. The bodies between which this tendency had been observed to take place were all round bodies, and either spherical or nearly so, but whether great or small, they seemed to gravitate toward one another according to the same law.

The planets gravitated to the sun, the moon to the earth, the satellites of Jupiter toward Jupiter; and gravity, in all these instances, varied inversely as the squares of the distances. Were the bodies ever so small—were they mere particles—provided only they were round, it was therefore safe to infer, that they would tend to unite with forces inversely as the squares of the distances. It was probable, then, that gravity was the mutual tendency of all the particles of matter toward one another; but this could not be concluded with certainty, till it was found, whether great spherical bodies composed of particles gravitating according to this law, would themselves gravitate according to the same. Perhaps no man of that age but Newton himself was fit to undertake the solution of this problem. His analysis, either in the form of fluxions or in that of prime and ultimate ratios, was able to reduce it to the quadrature of curves, and he then found, no doubt infinitely to his satisfaction, that the law was the same for the sphere as for the particles which composed it; that the gravitation was directed to the centre of the sphere, and was as the quantity of matter contained in it, divided by the square of the distance from its centre. Thus a complete expression was obtained for the law of gravity, involving both the conditions on which it must depend, the quantity of matter in the gravitating bodies, and the distance at which the bodies were placed. There could be no doubt that this tendency was always mutual, as there appeared nowhere any exception to the rule that action and reaction are equal; so that if a stone gravitated to the earth, the earth gravitated equally to the stone; that is to say, that the two bodies tended to approach one another with velocities which were inversely as their quantities of matter.[1] There appeared to be no limit to the distance to which this action reached; it was a force that united all the parts of matter to one another, and if it appeared to be particularly directed to certain points, such as the centres of the sun or of the planets, it was only on account of the quantity of matter collected and distributed uniformly round those points, through which, therefore, the force resulting from the composition of all those elements must pass either accurately or nearly.

A remarkable inference was deduced from this view of the planetary motions, giving a deep insight into the constitution of our system in a matter that seems the most recondite, and the furthest beyond the sphere which necessarily circumscribes human knowledge. The quantity of matter, and even the density of the planets, was determined. We have seen how Newton compared the intensity of gravitation at the surface of the earth, with its intensity at the moon, and by a computation somewhat similar, he compared the intensity of the earth's gravitation to the sun, with the moon's gravitation to the earth, each being measured by the contemporaneous and momentary deflexion from a tangent to the small arch of its orbit. A more detailed investigation showed that the intensity of the central force in different orbits, is as the mean distance divided by the square of the periodic time; and the same intensity being also as the quantities of matter divided by the squares of the distances, it follows, that these two quotients are equal to one another, and that, therefore, the quantities of matter are as the mean distances divided by the squares of the periodic times. Supposing, therefore, in the instance just mentioned, that the ratio of the mean distance of the sun from the earth to the mean distance of the moon from the earth is given (which it is from astronomical observation); as the ratio of their periodic lines is also known, the ratio of the quantity of matter in the sun to the quantity of matter in the earth, of consequence, is found, and the same holds good for all the planets which have satellites moving round them. Nothing certainly can be more unexpected than that the quantities of matter in bodies so remote, should admit of being compared with one another, and with the earth. Hence also their mean densities, or mean specific gravities, became known. For from their distances and the angles they subtended, both known from observation, their magnitudes or cubical contents were easily inferred, and the densities of all bodies are, as their quantities of matter, divided by their magnitude. The *Principia Philosophiæ Naturalis*, which contained all these discoveries, and established the principle of universal gravitation, was given to the world in 1687, an era, on that account, for ever memorable in the history of human knowledge.

---

[1] If M and M′ are the masses of two spheres, and x the distance of their centres, $\frac{M+M'}{x^2}$ is the accelerating force with which they tend to unite; but the velocity of the approach of M will be $\frac{M'}{x^2}$, and of M′, $\frac{M}{x^2}$.

The principle of gravity which was thus fully established, and its greatest and most extensive consequences deduced, was not now mentioned for the first time, though for the first time its existence as a fact was ascertained, and the law it observes was discovered. Besides some curious references to weight and gravity, contained in the writings of the ancients, we find something more precise concerning it in the writings of Copernicus, Kepler, and Hooke.

Anaxagoras is said to have held that "the heavens are kept in their place by the rapidity of their revolution, and would fall down if that rapidity were to cease."[1]

---

[1] Cœlum omne vehementi circuitu constare, alias remissione lapsurum. (Diog. Laert. *in Annax.* Lib. II. Sect. 12.)

Plutarch, in like manner, says, the moon is kept from falling by the rapidity of her motion, just as a stone whirled round in a sling is prevented from falling to the ground.[1]

Lucretius, reasoning probably after Democritus, holds, that the atoms would all from their gravity, have long since united in the centre of the universe, if the universe were not infinite so as to have no centre.[2]

An observation of Pythagoras, supposed to refer to the doctrine of gravity, though in reality extremely vague, has been abundantly commented on by Gregory and Maclaurin. A musical string, said that philosopher, gives the same sound with another of twice the length, if the latter be straitened by four times the weight that straitens the former; and the gravity of a planet is four times that of another which is at twice the distance. These are the most precise notices, as far as I know, that exist in the writings of the ancients concerning gravity as a force acting on terrestrial bodies, or as extending even to those that are more distant. They are the reveries of ingenious men who had no steady principles deduced from experience and observation to direct their inquiries; and who, even when in their conjectures they hit on the truth, could hardly distinguish it from error.

Copernicus, as might be expected, is considerably more precise. " I do not think," says he, " that gravity is any thing but a natural *appetency* of the parts (of the earth) given by the providence of the Supreme Being, that, by uniting together, they may assume the form of a globe. It is probable, that this same affection belongs to the sun, the moon, and the fixed stars, which all are of a round form."[3]

The power which Copernicus here speaks of has nothing to do, in his opinion, with the revolutions of the earth or the planets in their different orbits. It is merely intended as an explanation of their globular forms, and the consideration that does the author most credit is, that of supposing the force to belong, not to the centre, but to all the parts of the earth.

Kepler, in his immortal work on the *Motions of Mars,* treats of gravity as a force acting naturally from planet to planet, and particularly from the earth to the moon. " If the moon and the earth were not retained by some animal or other equivalent force each in its orbit, the earth would ascend to the moon by a 54th part of the interval between them, while the moon moved over the remaining 53 parts, that is supposing them both of the same density."[1] This passage is curious, as displaying a singular mixture of knowledge and error on the subject of the planetary motions. The tendency of the earth and moon being mutual, and producing equal quantities of motion in those bodies, bespeaks an accurate knowledge of the nature of that tendency, and of the equality, at least in this instance, between action and reaction. Then, again, the idea of an animal force or some other equally unintelligible power being necessary to carry on the circular motion, and to prevent the bodies from moving directly toward each other, is very strange; considering that Kepler knew the inertia of matter, and ought, therefore, to have understood the nature of centrifugal force, and its power to counteract the mutual gravitations of the two bodies. In this respect, the great astronomer who was laying the foundation of all that is known of the heavens, was not so far advanced as Anaxagoras and Plutarch;—so slow and unequal are the steps by which science advances to perfection. The mutual gravity of the earth and moon is not supposed by Kepler to have any concern in the production of their circular motions; yet he holds the tides to be produced by the gravitation of the waters of the sea toward the moon.[2]

---

[1] *De facie in Orbe Lunæ.*

[2] Lib. I v. 983.

[3] *Revolutionum,* Lib. I. cap. 9. p. 17.

The length to which Galileo advanced in this direction, and the point at which he stopped, are no less curious to be remarked. Though so well acquainted with the nature of gravity on the earth's surface,—the object of so many of his researches and discoveries, and though he conceived it to exist in all the planets, nay, in all the celestial bodies, and to be the cause of their round figure, he did not believe it to be a power that extended from one of those bodies to another. He seems to have thought that gravity was a principle which regulated the domestic economy of each particular body, but had nothing to do with their external relations; so that he censured Kepler for supposing, that the phenomena of the tides are produced by the gravitation of the waters of the ocean to the moon.[3]

Hooke did not stop short in the same unaccountable manner, but made a nearer approach to the truth than any one had yet done. In his attempt to prove the motion of the earth, published in 1674, he lays it down as the principle on which the celestial motions are to be explained, that the heavenly bodies have an attraction or gravitation toward their own centres, which extends to other bodies within the sphere of their activity; and that all bodies would move in straight lines, if some force like this did not act on them continually, and compel them to describe circles, ellipses, or other curve lines. The force of gravity, also, he considered as greatest nearest the body, though the law of its variation he could not determine. These are great advances;—though, from his mention of the sphere of activity, from his considering the force as residing in the centre, and from his ignorance of the law which it observed, it is evident, that beside great vagueness, there was much error in his notions about gravity. Hooke, however, whose candour and uprightness bore no proportion to the strength of his understanding, was disingenuous enough, when Newton had determined that law, to lay claim himself to the discovery.

---

[1] On that supposition their quantities of matter would be as their bulks, or as 1 to 53.

[2] *Astronomia Stellæ Martis.* Introd. Parag. 8

[3] Dial. 4to. Tom. IV. p. 325, Edit. de Padova.

This is the farthest advance that the knowledge of the cause of the celestial motions had made before the investigations of Newton, it is the precise point at which this knowledge had stopped; having met with a resistance which required a mathematician armed with all the powers of the new analysis to overcome. The doctrine of gravity was yet no more than a conjecture, of the truth or falsehood of which the measurements and reasonings of geometry could alone determine.

Thus, then, we are enabled accurately to perceive in what Newton's discovery consisted. It was in giving the evidence of demonstration to a principle which a few sagacious men had been sufficiently sharp-sighted to see obscurely or inaccurately, and to propose as a mere conjecture. In the history of human knowledge, there is hardly any discovery to which some gradual approaches had not been made before it was completely brought to light. To have found out the means of giving certainty to the thing asserted, or of disproving it entirely; and, when the *reality* of the principle was found out, to measure its quantity, to ascertain its laws, and to trace their consequences with mathematical precision,—in this consists the great difficulty and the great merit of such a discovery as that which is now before us. In this Newton had no competitor: envy was forced to acknowledge that he had no rival, and consoled itself with supposing that he had no judge.

Of all the physical principles that have yet been made known, there is none so fruitful in consequences as that of gravitation; but the same skill that had directed Newton to the discovery was necessary to enable him to trace its consequences.

The mutual gravitation of all bodies being admitted, it was evident, that while the planets were describing their orbits round the greatest and most powerful body in the system, they must mutually attract one another, and thence, in their revolutions, some irregularities, some deviations from the description of equal areas in equal times, and from the laws of the elliptic motion might be expected. Such irregularities, however, had not been observed at that time in the motion of any of the planets, except the moon, where some of them were so conspicuous as to have been known to Hipparchus and Ptolemy. Newton, therefore, was very naturally led to inquire what the different forces were, which, according to the laws just established, could produce irregularities in the case of the moon's motion. Beside the force of the earth, or rather of the mutual gravitation of the moon and earth, the moon must be acted on by the sun; and the same force which was sufficient to bend the orbit of the earth into an ellipse, could not but have a sensible effect on the orbit of the moon. Here Newton immediately observed, that it is not the whole of the force which the sun exerts on the moon that disturbs her motion round the earth, but only the difference between the force just mentioned, and that which the sun exerts on the earth,—for it is only that difference that affects the relative positions of the two bodies. To have exact measures of the disturbing forces, he supposed the entire force of the sun on the moon to be resolved into two, of which one always passed through the centre of the earth, and the other was always parallel to the line joining the sun and earth,—consequently, to the direction of the force of the sun on the earth. The former of these forces being directed to the centre of the earth, did not prevent the moon from describing equal areas in equal times round the earth. The effect of it on the whole, however, he showed to be, to diminish the gravity of the moon to the earth by about one 358th part, and to increase her mean distance in the same proportion, and her angular motion by about a 179th.

From the moon thus gravitating to the centre of the earth, not by a force that is altogether inversely as the square of the distance, but by such a force diminished by a small part that varies simply as the distance, it was found, from a very subtle investigation, that the dimensions of the elliptic orbit would not be sensibly changed, but that the orbit itself would be rendered moveable, its longer axis having an angular and progressive motion, by which it advanced over a certain arc during each revolution of the moon. This afforded an explanation of the motion of the apsides of the lunar orbit which had been observed to go forward at the rate of 3° 4′, nearly, during the time of the moon's revolution, in respect of the fixed stars.

This was a new proof of the reality of the principle of gravitation, which, however, was rendered less conclusive by the consideration that the exact quantity of the motion of the apsides observed, did not come out from the diminution of the moon's gravity as above assigned. There was a sort of cloud, therefore, which hung over this point of the lunar theory, to dissipate which, required higher improvements in the calculus than it was given to the inventor himself to accomplish. It was not so with respect to another motion to which the plane of the lunar orbit is subject, a phenomenon which had been long known in consequence of its influence on the eclipses of the sun and moon. This was the retrogradation of the line of nodes, amounting to 3′ 10″ every day. Newton showed that the second of the forces into which the solar action is moved being exerted, not in the plane of the moon's orbit, but in that of the ecliptic, inclined to the former at an angle somewhat greater than five degrees, its effect must be to draw down the moon to the plane of the ecliptic sooner than it would otherwise arrive at it; in consequence of which, the intersection of the two planes would approach, as it were, toward the moon, or move in a direction opposite to that of the moon's motion, or become retrograde. From the quantity of the solar force, and the inclination of the moon's orbit, Newton determined the mean quantity of this retrogradation, as well as the irregularities to which it is subject, and found both to agree very accurately with observation.

Another of the lunar inequalities,—that discovered by Tycho, and called by him the *Variation,* which consists in the alternate acceleration and retardation of the moon in each quarter of her revolution, was accurately determined from theory, such as it is found by observation; and the same is true as to the annual equation, which had been long confounded with the equation of time. With regard to the other inequalities, it does not appear that Newton attempted an exact determination of them, but satisfied himself with this general truth, that the principle of the sun's disturbing force led to the supposition of inequalities of the same kind with those actually observed, though whether of the same exact quantity it must be difficult to determine. It was reserved, indeed, for a more perfect state of the calculus to explain the whole of those irregularities, and to deduce their precise value from the theory of gravity. Theory has led to the knowledge of many inequalities, which observation alone would have been unable to discover.

While Newton was thus so successfully occupied in tracing the action of gravity among those distant bodies, he did not, it may be supposed, neglect the consideration of its effects on the objects which are nearer us, and particularly on the Figure of the Earth. We have seen that, even with the limited views and imperfect information which Copernicus possessed on this subject, he ascribed the round figure of the earth and of the planets to the force of gravity residing in the particles of these bodies. Newton, on the other hand, perceived that, in the earth, another force was combined with gravity, and that the figure resulting from that combination could not be exactly spherical. The diurnal revolution of the earth, he knew, must produce a centrifugal force, which would act most powerfully on the parts most distant from the axis. The amount of this centrifugal force is greatest at the equator, and being measured by the momentary recess of any point from the tangent, which was known from the earth's rotation, it could be compared with the force of gravity at the same place, measured in like manner by the descent of a heavy body in the first moment of its fall. When Newton made this comparison, he found that the centrifugal force at the equator is the 289th part of gravity, diminishing continually as the cosine of the latitude, on going from thence toward the poles, where it ceases altogether. From the combination of this force, though small, with the force of gravity, it follows, that the line in which bodies actually gravitate, or the plumb-line, cannot tend exactly to the earth's centre, and that a true horizontal line, such as is drawn by levelling, if continued from either pole, in the plane of a meridian all round the earth, would not be a circle but an ellipse, having its greatest axis in the plane of the equator, and its least in the direction of the axis of the earth's rotation. Now, the surface of the ocean itself actually traces this level as it extends from the equator to either pole. The terraqueous mass which we call the globe, must therefore be what geometers call an oblate spheroid, or a solid generated by the revolution of the elliptic meridian about its shorter axis.

In order to determine the proportion of the axes of this spheroid, a problem, it will readily be believed, of no ordinary difficulty, Newton conceived, that if the waters at the pole and at the equator were to communicate by a canal through the interior of the earth, one branch reaching from the pole to the centre and the other at right angles to it, from the centre to the circumference of the equator, the water in this canal must be *in equilibrio*, or the weight of fluid in the one branch just equal to that in the other. Including, then, the consideration of the centrifugal force which acted on one of the branches but not on the other, and considering, too, that the figure of the mass being no longer a sphere, the attraction must not be supposed to be directed to the centre, but must be considered as the result of the action of all the particles of the spheroid on the fluid in the canals; by a very subtle process of reasoning, Newton found that the longer the two canals must be to the shorter as 230 to 229. This, therefore, is the ratio of the radius of the equator to the polar semiaxis, their difference amounting, according to the dimensions then assigned to the earth, to about $17\frac{1}{10}$ English miles.

In this investigation, the earth is understood to be homogeneous, or everywhere of the same density.

It is very remarkable, that though the ingenious and profound reasoning on which this conclusion rests is not entirely above objection, and assumes some things without sufficient proof, yet, when these defects were corrected in the new investigations of Maclaurin and Clairaut, the conclusion, supposing the earth homogeneous, remained exactly the same. The sagacity of Newton, like the *Genius* of Socrates, seemed sometimes to inspire him with wisdom from an invisible source. By a profound study of nature, her laws, her analogies, and her resources, he seems to have acquired the same sort of *tact* or *feeling* in matters of science, that experienced engineers and other artists sometimes acquire in matters of practice, by which they are often directed right, when they can scarcely describe in words the principle on which they proceed.

From the figure of the earth thus determined, he showed that the intensity of gravity at any point of the surface, is inversely as the distance of that point from the centre; and its increase, therefore, on going from the equator to the poles, is as the square of the sine of the latitude, the same ratio in which the degrees of the meridian increase.[1] As the intensity of gravity diminished on going from the poles to the equator, or from the higher to the lower latitudes, it followed, that a pendulum of a given length would vibrate slower when carried from Europe into the torrid zone. The observations of the two French astronomers, Varin and De Hayes, made at Cayenne and Martinique, had already confirmed this conclusion.

The problem which Newton had thus resolved enabled him to resolve one of still greater difficulty. The precession, that is, the retrogradation of the equinoctial points, had been long known to astronomers; its rate had been measured by a comparison of ancient and modern observations, and found to amount nearly to 50″ annually, so as to complete an entire revolution of the heavens in 25,920 years. Nothing seemed more difficult to explain than this phenomenon, and no idea of assigning a physical or mechanical cause for it had yet occurred, I believe, to the boldest and most theoretical astronomer. The honour of assigning the true cause was reserved for the most cautious of philosophers. He was directed to this by a certain analogy observed between the precession of the equinoxes and the retrogradation of the moon's nodes, a phenomenon to which his calculus had been already successfully applied. The spheroidal shell or ring of matter which surrounds the earth, as we have just seen, in the direction of the equator, being one half above the plane of the ecliptic and the other half below, is subjected to the action of the solar force, the tendency of which is to make this ring turn on the line of its intersection with the ecliptic, so as ultimately to coincide with the plane of that circle. This, accordingly, would have happened long since, if the earth had not revolved on its axis. The effect of the rotation of the spheroidal ring from west to east, at the same time that it is drawn down toward the plane of the ecliptic, is to preserve the inclination of these two planes unchanged, but to make their intersection move in a direction opposite to that of the diurnal rotation, that is, from east to west, or contrary to the order of the signs.

---

[1] *Princip.* Lib. III. prop. 20.

The calculus in its result justified this general conclusion ; 10″ appeared the part of the effect due to the moon's attraction, 40″ to the attraction of the sun; and I know not if there be any thing respecting the constitution of our system, in which this great philosopher gave a stronger proof of his sagacity and penetration, than in the explanation of this phenomenon. The truth, however, is, that his data for resolving the problem were in some degree imperfect, all the circumstances were not included, and some were erroneously applied, yet the great principle and scope of the solution were right, and the approximation very near to the truth. "Il a été bien servi par son genie," says the eloquent and judicious historian of astronomy ; "l'inspiration de cette faculté divine lui a fait appercevoir des determinations, qui n'etoient pas encore accessibles ; soit qu'il eût des preuves qu'il a supprimées, *soit qu'il eût dans l'esprit un sorte d'estime, une espèce de balance pour approuver certaines vérités, en pesant les verités prochaines, et jugeant les unes par les autres.*"[1]

It was reserved for a more advanced condition of the new analysis, to give to the solution of this problem all the accuracy of which it is susceptible. It is a part, and a distinguishing part, of the glory of this system, that it was susceptible of more perfection than it received from the hands of the author ; and that the century and a half which has nearly elapsed since the first discovery of it has been continually adding to its perfection. This character belongs to a system which has truth and nature for its basis, and had not been exhibited in any of the physical theories that had yet appeared in the world. The philosophy of Plato and Aristotle were never more perfect than when they came from the hands of their respective authors, and a legion of commentators, with all their efforts, did nothing but run round perpetually in the same circle.

---

[1] Bailly, *Hist. de l'Astron. Mod.* Tom. II. livre xii. § 28.

Even Descartes, though he had recourse to physical principles, and tried to fix his system on a firmer basis than the mere abstractions of the mind, left behind him a work which not only could not be improved, but was such, that every addition attempted to be made destroyed the equilibrium of the mass, and pulled away the part to which it was intended that it should be attached. The philosophy of Newton has proved susceptible of continual improvement; its theories have explained facts quite unknown to the author of it; and the exertions of La Grange and La Place, at the distance of an hundred years, have perfected a work which it was not for any of the human race to begin and to complete.

Newton next turned his attention to the phenomena of the Tides, the dependence of which on the moon, and in part also on the sun, was sufficiently obvious even from common observation. That the moon is the prime ruler of the tide, is evident from the fact, that the high water, at any given place, occurs always nearly at the moment when the moon is on the same meridian, and that the retardation of the tide from day to day, is the same with the retardation of the moon in her diurnal revolution. That the sun is also concerned in the production of the tides is evident from this, that the highest tides happen when the sun, the moon, and the earth, are all three in the same straight line; and that the lowest, or neap tides, happen when the lines drawn from the sun and moon to the earth make right angles with one another. The eye of Newton, accustomed to generalize and to penetrate beyond the surface of things, saw that the waters of the sea revolving with the earth, are nearly in the condition of a satellite revolving about its primary; and are liable to the same kind of disturbance from the attraction of a third body. The fact in the history of the tides which seems most difficult to be explained, received, on this supposition, a very easy solution. It is known, that high water always takes place in the hemisphere where the moon is, and in the opposite hemisphere where the moon is not, nearly at the same time. This seems, at first sight, very unlike an effect of the moon's attraction; for, though the water in the hemisphere where the moon is, and which, therefore, is nearest the moon, may be drawn up toward that body, the same ought not to happen in the opposite hemisphere, where the earth's surface is most distant from the moon. But if the action of the moon disturb the equilibrium of the ocean, just as the action of one planet disturbs the motion of a satellite moving round another, it is exactly what might be expected. It had been shown, that the moon, in conjunction with the sun, has her gravitation to the earth diminished, and when in opposition to the sun has it diminished very nearly by the same quantity. The reason is, that at the conjunction, or the new moon, the moon is drawn to the sun more than the earth is; and that, at the opposition, or full moon, the earth is drawn toward the sun more than the moon nearly by the same quantity; the relative motion of the two bodies is therefore affected the same way in both cases, and the gravity of the moon to the earth, or her tendency to descend toward it, is in both cases lessened.

It is plain, that the action of the moon on the waters of the ocean must be regulated by the same principle. In the hemisphere where the moon is, the water is more drawn toward the moon than the mass of the earth is, and its gravity being lessened, the columns toward the middle of the hemisphere lengthen, in consequence of the pressure of the columns which are at a distance from the middle point, of which the weight is less diminished, and towards the horizon must even be increased. In the opposite hemisphere, again, the mass of the earth is more drawn to the moon than the waters of that hemisphere, and their relative tendencies are changed in the same direction, and nearly by the same quantity If the action of the moon on all the parts of the earth, both sea and land, were the same, no tide whatever would be produced.

Thus, the same analysis of the force of gravity which explained the inequalities of the moon, were shown by Newton to explain those inequalities in the elevation of the waters of the ocean to which we give the name of tides. On the principle also explained in this analysis, it is, that the attraction of the sun and moon conspire to elevate the waters of the ocean whether these luminaries be in opposition or conjunction In both cases the solar and lunar tides are added together, and the tide actually observed is their sum. At the quadratures, or the first and third quarters, these two tides are opposed to one another, the high water of the lunar tide coinciding with the low water of the solar, and conversely, so that the tide actually observed is the difference of the two.

The other phenomena of the tides were explained in a manner no less satisfactory, and it only remained to inquire. Whether the quantity of the solar and lunar forces were adequate to the effect thus ascribed to them? The lunar force there were yet no data for measuring, but a measure of the solar force, as it acts on the moon, had been obtained, and it had been shown that in its mean quantity it amounted to $\frac{1}{178}$ of the force which retains the moon in her orbit. This last is $\frac{1}{3600}$ of the force of gravity at the earth's surface, and therefore, the force with which the sun disturbs the moon's motion is $\frac{1}{178} \times \frac{1}{3600}$ of gravity at the earth's surface. This is the solar disturbing force on the moon when distant sixty semidiameters from the earth's centre, but on a body only one semidiameter distant from that centre, that is, on the water of the ocean, the disturbing force would be sixty times less, and thus is found to be no more than $\frac{1}{38448000}$ of gravity at the earth's surface.

Now, this being the mean force of the sun, is that by which he acts on the waters, 90 degrees distant from the point to which he is vertical, where it is added to the force of gravity, and tends to increase the weight and lower the level of the waters. At the point where the sun is vertical, the force to raise the water is about double of this, and, therefore, the whole force tending to raise the level of the high, above that of the low water, is three times the preceding, or about the $\frac{1}{12816000}$ of gravity. Small as this force is, when it is applied to every particle of the ocean, it is capable of producing a sensible effect. The manner in which Newton estimates this effect can only be considered as affording an approximation to the truth. In treating of the figure of the earth, he had shown that the centrifugal force, amounting to $\frac{1}{289}$ of gravity, was able to raise the level of the ocean more than seventeen miles, or, more exactly, 85,472 French feet. Hence, making the effect proportional to the forces, the elevation of the waters produced by the solar force will come out 1.92 feet.

But, from the comparison of the neap and spring tides, that is, of the difference and the sum of the lunar and solar forces, it appears, that the force of the moon is to that of the sun as 4.48 to 1. As the solar force raises the tide 1.92 feet, the lunar will raise it 8.63 feet, so that the two together will produce a tide of 10.½ [1] French feet, which agrees not ill with what is observed in the open sea, at a distance from land.

The calculus of Newton stopped not here. From the force that the moon exerts on the waters of the ocean, he found the quantity of matter in the moon to that in the earth as 1 to 39.78, or, in round numbers, as 1 to 40. He also found the density of the moon to the density of the earth as 11 to 9.

Subsequent investigations, as we shall have occasion to remark, have shown that much was yet wanting to a complete theory of the tides; and that even after Maclaurin, Bernoulli, and Euler,[2] had added their efforts to those of Newton, there remained enough to give full employment to the calculus of Laplace. As an original deduction, and as a first approximation, that of which I have now given an account will be for ever memorable.

---

[1] Newtoni *Prin.* Lib. III. Prop. 36 ad 37.

[2] See the solutions of these three mathematicians in the *Commentary* of Le Seur and Jacquier on the Third Book of the *Principia*.

The motion of Comets yet remained to be discussed. They had only lately been acknowledged to belong to the heavens, and to be placed beyond the region of the earth's atmosphere; but with regard to their motion, astronomers were not agreed. Kepler believed them to move in straight lines; Cassini thought they moved in the planes of great circles, but with little curvature. Hevelius had come much nearer the truth; he had shown the curvature of their paths to be different in different parts, and to be greatest when they were nearest the sun; and a parabola having its vertex in that point seemed to him to be the line in which the comet moved. Newton, convinced of the universality of the principle of gravitation, had no doubt that the orbit of the comet must be a conic section, having the sun in one of its foci, and might either be an ellipse, a parabola, or even an hyperbola, according to the relation between the force of projection and the force tending to the centre. As the eccentricity of the orbit on every supposition must be great, the portion of it that fell within our view could not differ much from a parabola, a circumstance which rendered the calculation of the comet's place, when the position of the orbit was once ascertained, more easy than in the case of the planets. Thus far theory proceeded, and observation must then determine with what degree of accuracy this theory represented the phenomena. From three observations of the comet, the position of the orbit could be determined, though the geometric problem was one of great difficulty. Newton gave a solution of it; and it was by this that his theory was to be brought to the test of experiment. If the orbit thus determined was not the true one, the places of the comet calculated on the supposition that it was, and that it described equal areas in equal times about the sun, could not agree with the places actually observed. Newton showed, by the example of the remarkable comet then visible (1680), that this agreement was as great as could reasonably be expected; thus adding another proof to the number of those already brought to support the principle of universal gravitation. The comets descend into our system from all different quarters in the heavens, and, therefore, the proofs that they afforded went to show, that the action of gravity was confined to no particular region of the heavens.

Thus far Newton proceeded in ascertaining the existence, and in tracing the effects, of the principle of gravitation, and had done so with a success of which there had been no instance in the history of human knowledge. At the same time that it was the most successful, it was the most difficult research that had yet been undertaken. The reasonings upward from the facts to the general principle, and again down from that principle to its effects, both required the application of a mathematical analysis which was but newly invented; and Newton had not only the difficulties of the investigation to encounter, but the instrument to invent, without which the investigation could not have been conducted. Every one who considers all this, will readily join in the sentiment with which Bailly closes a eulogy as just as it is eloquent. *Si, comme Platon a pensé, il existoit dans la nature une echelle d'etres et de substances intelligentes jusqu'à l'Etre Supremê, l'espéce humaine, defendant ses droits, auroit une foule de grands hommes à presenter; mais Newton, suivi de ses vérités pures, montreroit le plus haut degré de force de l'esprit humain, et suffiroit seul pour lui assigner sa vrai place.*[1]

Though the creative power of genius was never more clearly evinced than in the discoveries of this great philosopher, yet the influence of circumstances, always extensive and irresistible in human affairs, can readily be traced. The condition of knowledge at the time when Newton appeared was favourable to great exertions; it was a moment when things might be said to be prepared for a revolution in the mathematical and physical sciences. The genius of Copernicus had unfolded the true system of the world; and Galileo had shown its excellence, and established it by arguments, the force of which were generally acknowledged. Kepler had done still more, having, by an admirable effort of generalisation, reduced the facts concerning the planetary motions to three general laws. Cassini's observations had also extended the third of these laws to the satellites of Jupiter, showing that the squares of their periodic times were as the cubes of their distances from the centre of the body round which they revolved. The imaginary apparatus of cycles and epicycles,—the immobility of the earth,—the supposed essential distinction between celestial and terrestrial substances, those insuperable obstacles to real knowledge, which the prejudice of the ancients had established as physical truths, were entirely removed; and Bacon had taught the true laws of philosophising, and pointed out the genuine method of extracting knowledge from experiment and observation. The leading principles of mechanics were established; and it was no unimportant circumstance, that the *Vortices* of Descartes had exhausted one of the sources of error, most seducing on account of its simplicity.

All this had been done when the genius of Newton arose upon the earth. Never till now had there been set before any of the human race so brilliant a career to run, or so noble a prize to be obtained. In the progress of knowledge, a moment had arrived more favourable to the developement of talent than any other, either later or earlier, and in which it might produce the greatest possible effect. But, let it not be supposed, while I thus admit the influence of external circumstances on the exertions of intellectual power, that I am lessening the merit of this last, or taking any thing from the admiration that is due to it. I am, in truth, only distinguishing between what it is possible, and what it is impossible, for the human mind to effect. With all the aid that circumstances could give, it required the highest degree of intellectual power to accomplish what Newton performed. We have here a memorable, perhaps a singular instance, of the highest degree of intellectual power, united to the most favourable condition of things for its exertion. Though Newton's situation was more favourable than that of the men of science who had gone before him, it was not more so than that of those men who pursued the same objects at the same time with himself, placed in a situation equally favourable.

---

[1] *Hist. de l'Astron. Mod.* Tom. II.

When one considers the splendour of Newton's discoveries, the beauty, the simplicity, and grandeur of the system they unfolded, and the demonstrative evidence by which that system was supported, one could hardly doubt, that, to be received, it required only to be made known, and that the establishment of the Newtonian philosophy all over Europe would very quickly have followed the publication of it. In drawing this conclusion, however, we should make much too small an allowance for the influence of received opinion, and the resistance that mere habit is able, for a time, to oppose to the strongest evidence. The Cartesian system of vortices had many followers in all the countries of Europe, and particularly in France. In the universities of England, though the Aristotelian physics had made an obstinate resistance, they had been supplanted by the Cartesian, which became firmly established about the time when their foundation began to be sapped by the general progress of science, and particularly by the discoveries of Newton. For more than thirty years after the publication of those discoveries, the system of vortices kept its ground, and a translation from the French into Latin of the *Physics* of Rohault, a work entirely Cartesian, continued at Cambridge to be the text for philosophical instruction. About the year 1718, a new and more elegant translation of the same book was published by Dr Samuel Clarke, with the addition of notes, in which that profound and ingenious writer explained the views of Newton on the principal objects of discussion, so that the notes contained *virtually* a refutation of the text; they did so, however, only virtually, all appearance of argument and controversy being carefully avoided. Whether this escaped the notice of the learned Doctors or not is uncertain, but the new translation, from its better Latinity, and the name of the editor, was readily admitted to all the academical honours which the old one had enjoyed. Thus, the stratagem of Dr Clarke completely succeeded; the tutor might prelect from the text, but the pupil would sometimes look into the notes, and error is never so sure of being exposed as when the truth is placed close to it, side by side, without any thing to alarm prejudice, or awaken from its lethargy the dread of innovation. Thus, therefore, the *Newtonian* philosophy first entered the university of Cambridge under the protection of the *Cartesian.*[1]

If such were the obstacles to its progress that the new philosophy experienced in a country that was proud of having given birth to its author, we must expect it to advance very slowly indeed among foreign nations. In France, we find the first astronomers and mathematicians, such men as Cassini and Maraldi, quite unacquainted with it, and employed in calculating the paths of the comets they were observing on hypotheses the most unfounded and imaginary; long after Halley, following the principles of Newton, had computed tables from which the motions of all the comets that ever had appeared, or ever could appear, might be easily deduced. Fontenelle, with great talents and enlarged views, and, as one may say, officially informed of the progress of science all over Europe, continued a Cartesian to the end of his days. Mairan in his youth was a zealous defender of the vortices, though he became afterwards one of the most strenuous supporters of the doctrine of gravitation.

A Memoir of the Chevalier Louville, among those of the Academy of Sciences for 1720, is the first in that collection, and, I believe, the first published in France, where the elliptic motion of the planets is supposed to be produced by the combination of two forces, one projectile and the other centripetal. Maupertuis soon after went much farther; in his elegant and philosophic treatise, *Figure des Astres*, published about 1730, he not only admitted the existence of attraction as a fact, but even defended it, when considered as an universal property of body, against the reproach of being a metaphysical absurdity. These were considerable advances, but they were made slowly; and it was true, as Voltaire afterwards remarked, that though the author of the *Principia* survived the publication of that great work nearly forty years, he had not, at the time of his death, twenty followers out of England.

---

[1] The universities of St Andrews and Edinburgh were, I believe, the first in Britain where the Newtonian philosophy was made the subject of the academical prelections. For this distinction they are indebted to James and David Gregory, the first in some respects the rival, but both the friends of Newton. Whiston bewails in the anguish of his heart the difference in this respect between those universities and his own. David Gregory taught in Edinburgh for several years prior to 1690, when he removed to Oxford; and Whiston says, " He had already caused several of his scholars to keep acts, as we call them, upon several branches of the Newtonian philosophy, while we at Cambridge (poor wretches) were ignominiously studying the fictitious hypotheses of the Cartesian." (Whiston's *Memoirs of his own Life.*) I do not, however, mean to say, that from this date the Cartesian philosophy was expelled from those universities; the *Physics* of Rohault were still in use as a text, at least occasionally, to a much later period than this, and a great deal, no doubt, depended on the character of the individual professors. Keil introduced the Newtonian philosophy in his lectures at Oxford in 1697; but the instructions of the tutors, which constitute the real and efficient system of the university, were not cast in that mould till long afterwards. The publication of S'Gravesende's *Elements* proves that the Newtonian philosophy was taught in the Dutch universities before the date of 1720.

We should do wrong, however, to attribute this slow conversion of the philosophic world entirely to prejudice, inertness, or apathy. The evidence of the Newtonian philosophy was of a nature to require time in order to make an impression. It implied an application of mathematical reasoning which was often difficult; the doctrine of prime and ultimate ratios was new to most readers, and could be familiar only to those who had studied the infinitesimal analysis.

The principle of gravitation itself was considered as difficult to be admitted. When presented indeed as a mere fact, like the weight of bodies at the earth's surface, or their tendency to fall to the ground, it was free from objection; and it was in this light only that Newton wished it to be considered.[1] But though this appears to be the sound and philosophical view of the subject, there has always appeared a strong desire in those who speculated concerning gravitation to go farther, and to inquire into the cause of what, as a mere fact, they were sufficiently disposed to admit. If you said that you had no explanation to give, and was only desirous of having the fact admitted; they alleged, that this was an unsatisfactory proceeding,—that it was admitting the doctrine of *occult causes*,—that it amounted to the assertion, that bodies acted in places where they were not,—a proposition that, metaphysically considered, was undoubtedly absurd. The desire to explain gravitation is indeed so natural, that Newton himself felt its force, and has thrown out, at the end of his *Optics*, some curious conjectures concerning this general affection of body, and the nature of that elastic ether to which he thought that it was perhaps to be ascribed. " Is not this medium (the ether) much rarer within the dense bodies of the sun, stars, and planets, than in the empty celestial spaces between them? And, in passing from them to great distances, does it not grow denser and denser perpetually, and thereby cause the gravity of those great bodies to one another, every body endeavouring to go from the denser parts of the medium to the rarer?"[1]

---

[1] " *Vocem attractionis hic generalitor usurpo pro corporum conatu quocunque accedendi ad invicem; sive conatus iste fiat ab actione corporum se mutuo petentium, vel per spiritus emissos se mutuo agitantium; sive is ab actione ætheris, aut aeris medii cujuscunque, corporei vel incorporei oritur, corpora innatantia in si invicem utcunque impellentes.*" *Principia Math.* Lib. I. *Schol. ad finem.* prop. 69.

Notwithstanding the highest respect for the author of these conjectures, I cannot find any thing like a satisfactory explanation of gravity in the existence of this elastic ether. It is very true that an elastic fluid, of which the density followed the inverse ratio of the distance from a given point, would urge the bodies immersed in it, and impervious to it, toward that point with forces inversely as the squares of the distances from it; but what could maintain an elastic fluid in this condition, or with its density varying according to this law, is a thing as inexplicable as the gravity which it was meant to explain. The nature of an elastic fluid must be, in the absence of all inequality of pressure, to become every where of the same density. If the causes that produce so marked and so general a deviation from this rule be not assigned, we can only be said to have substituted one difficulty for another.

A different view of the matter was taken by some of the disciples and friends of Newton, but which certainly did not lead to any thing more satisfactory. This philosopher himself had always expressed his decided opinion[2] that gravity could not be considered as a property of matter; but Mr Cotes, in the preface to the second edition of the *Principia*, maintains, that gravity is a property which we have the same right to ascribe to matter, that we have to ascribe to it extension, impenetrability, or any other property. This is said to have been inserted without the knowledge of

---

[1] *Optics*, Query 21, at the end of the Third Book.

[2] The passages quoted sufficiently prove that Newton did not consider gravity as a property inherent in matter. The following passage in one of his Letters to Dr Bentley is still more explicit: " It is inconceivable that inanimate brute matter should, without the mediation of something else, which is not material, operate upon and affect other matter without mutual contact; as it must do, if gravitation, in the sense of Epicurus, be essential or inherent in it. That gravity should be innate, inherent, and essential to matter, so that one body may act on another, at a distance, through a vacuum, without the mediation of any thing else, by and through which their action and force may be conveyed from one to another, is, to me, so great an absurdity, that I believe no man who, in philosophical matters, has a competent faculty of thinking can ever fall into it." (*Newtoni Opera*, Tom. IV. Horseley's edit. p. 438.) On this passage I cannot help remarking, that it is not quite clear in what manner the interposition of a material substance can convey the action of distant bodies to one another. In the case of percussion or pressure, this is indeed very intelligible, but it is by no means so in the case of attraction. If two particles of matter, at opposite extremities of the diameter of the earth, attract one another, this effect is just as little intelligible, and the *modus agendi* is just as mysterious, on the supposition that the whole globe of the earth is interposed, as on that of nothing whatever being interposed, or of a complete vacuum existing between them. It is not enough that each particle attracts that in contact with it; it must attract the particles that are distant, and the intervention of particles between them does not render this at all more intelligible.

Newton,—a freedom which it is difficult to conceive that any man could use with the author of the *Principia*. However that be, it is certain that these difficulties have been always felt, and had their share in retarding the progress of the philosophy to which they seemed to be inseparably attached.

There were other arguments of a less abstruse nature, and more immediately connected with experiment, which, for a time, resisted the progress of the Newtonian philosophy, though they contributed, in the end, very materially to its advancement. Nothing, indeed, is so hostile to the interests of truth, as facts inaccurately observed; of which we have a remarkable example in the measurement of an arch of the meridian across France, from Amiens to Perpignan, though so large as to comprehend about seven degrees, and though executed by Cassini, one of the first astronomers in Europe. According to that measurement, the degrees seemed to diminish on going from south to north, each being less by about an 800th part than that which immediately preceded it toward the south. From this result, which is entirely erroneous, the conclusion first deduced was correct, the error in the reasoning, by a very singular coincidence, having corrected the error in the *data* from which it was deduced. Fontenelle argued that, as the degrees diminished in length, on going toward the poles, the meridian must be less than the circumference of the equator, and the earth, of course, swelled out in the plane of that circle, agreeably to the facts that had been observed concerning the retardation of the pendulum when carried to the south. This, however, was the direct contrary of the conclusion which ought to have been drawn, as was soon perceived by Cassini and by Fontenelle himself. The degrees growing less as they approached the pole, was an indication of the curvature growing greater, or of the longer axis of the meridian being the line that passed through the poles, and that coincided with the axis of the earth. The figure of the earth must, therefore, be that of an oblong spheroid, or one formed by the revolution of an ellipsis about its longer axis. This conclusion seemed to be strengthened by the prolongation of the meridian from Amiens northward to Dunkirk in 1713, as the same diminution was observed; the medium length of the degree between Paris and Dunkirk being 56970 toises, no less than 137 less than the mean of the degrees toward the south.[1] All this seemed quite inconsistent with the observations on the pendulum, as well as with the conclusions which Newton had deduced from the theory of gravity. The Academy of Sciences was thus greatly perplexed, and uncertain to what side to incline. In these circumstances, J. Cassini, whose errors were the cause of all the difficulty, had the merit of suggesting the only means by which the question concerning the figure of the earth was likely to receive a satisfactory solution,—the measurement of two degrees, the one under the equator, and the other as near to the pole as the nature of the thing would admit. But it was not till considerably beyond the limits of the period of which I am now treating, that these measures were executed; and that the increase of the degrees toward the poles, or the oblateness of the earth's figure, was completely ascertained. Cassini, on resuming his own operations, discovered, and candidly acknowledged, the errors in his first measurement; and thus the objections which had arisen in this quarter against the theory of gravity became irresistible arguments in its favour. This subject will occupy much of our attention in the history of the *second period,* till which, the establishment of the Newtonian philosophy on the Continent cannot be said to have been accomplished.

---

[1] *Memoires de l'Acad. des Sciences*, 1718, p. 245.

In addition to these discoveries in physical astronomy, this period affords several on the descriptive parts of the science, of which, however, I can only mention one, as far too important to be passed over in the most general outline. It regards the apparent motion in the fixed stars, known by the name of the Aberration, and is the discovery of Dr Bradley, one of the most distinguished astronomers of whom England has to boast. Bradley and his friend Molyneux, in the end of the year 1725,[1] were occupied in searching for the parallax of the fixed stars by means of a zenith sector, constructed by Graham, the most skilful instrument maker of that period. The sector was erected at Kew; it was of great radius, and furnished with a telescope twenty-four feet in length, with which they proposed to observe the transits of stars near the zenith, according to a method that was first suggested by Hooke, and pursued by him so far as to induce him to think that he had actually discovered the parallax of γ *Draconis,* the bright star in the head of the dragon, on which he made his observations. They began their observations of the transits of the same star on the 3d of December, when the distance from the zenith at which it passed was carefully marked. By the observations of the subsequent days the star seemed to be moving to the south; and about the beginning of March, in the following year, it had got $20''$ to the south, and was then nearly stationary. In the beginning of June it had come back to the same situation where it was first observed, and from thence it continued its motion northward till September, when it was about 20″ north of the point where it was first seen, its whole change of declination having amounted to 40″.

---

[1] *Phil. Trans.* Vol. XXXV. p. 697.

This motion occasioned a good deal of surprise to the two observers, as it lay the contrary way to what it would have done if it had proceeded from the parallax of the star. The repetition of the observations, however, confirmed their accuracy; and they were afterwards pursued by Dr Bradley, with another sector constructed also by Graham, of a less radius, but still of one sufficiently great to measure a star's zenith distance to half a second. It embraced a larger arch, and admitted of the observations being extended to stars that passed at a more considerable distance from the zenith.

Even with this addition the observations did not put Bradley in possession of the complete fact, as they only gave the motion of each star in declination, without giving information about what change might be produced in its right ascension.

Had the whole fact, that is, the motion in right ascension as well as in declination been given from observation, it could not have been long before the cause was discovered. With such information, however, as Dr Bradley had, that discovery is certainly to be regarded as a great effort of sagacity. He has not told us the steps by which he was led to it; only we see that, by the method of exclusion, he had been careful to narrow the field of hypothesis, and had assured himself that the phenomenon was not produced by any nutation of the earth's axis; by any change in the direction of the plumb-line, or by refraction of any kind. All these causes being rejected, it occurred to him that the appearances might arise from the progressive motion of light combined with the motion of the earth in its orbit. He reasoned somewhat in this manner. If the earth were at rest, it is plain that a telescope, to admit a ray of light coming from a star to pass along its axis, must be directed to the star itself. But, if the earth, and, of course, the telescope be in motion, it must be inclined forward, so as to be in the diagonal of a parallelogram, the sides of which represent the motion of the earth, and the motion of light, or in the direction of those motions, and in the ratio of their velocities. It is with the telescope just as with the vane at the mast-head of a ship; when the ship is at anchor, the vane takes exactly the direction of the wind: when the ship is under weigh, it places itself in the diagonal of a parallelogram, of which one side represents the velocity of the ship, and the other the velocity of the wind. If, instead of the vane, we conceive a hollow tube, moveable in the same manner, the case will become more exactly parallel to that of the telescope. The tube will take such a position that the wind may blow through it without striking against the sides, and its axis will then be the diagonal of the parallelogram just referred to.

The telescope, therefore, through which a star is viewed, and by the axis of which its position star is determined, must make an angle with the straight line drawn to the star, except when the earth moves directly upon the star, or directly from it. Hence it follows, that if the star be in the pole of the ecliptic, the telescope must be pointed forward, in the direction of the earth's motion, always by the same angle, so that the star would be seen out of its true place by that angle, and would appear to describe a circle round the pole of the ecliptic, the radius of which, subtended at the earth, an angle, of which the sine is to unity, as the velocity of the earth to the velocity of light. If the star be any where between the plane of the ecliptic and the pole, its apparent path will be an ellipse, the longer axis of which is the same with the diameter of the former circle, and the shorter equal to the same quantity, multiplied by the sine of the star's latitude. If the star be in the plane of the ecliptic, this shorter axis vanishes, and the apparent path of the star is a straight line, equal to the axis just mentioned.

Bradley saw that Römer's observation concerning the time that light takes to go from the sun to the earth gave a ready expression for the velocity of light compared with that of the earth. The proportion, however, which he assumed as best suited to his observations was somewhat different; it was that of 10313 to 1, which made the radius of the circle of aberration 20″, and the transverse axis of the ellipse in every case, or the whole change of position, 40″. It was the shorter axis which Bradley had actually observed in the case of γ *Draconis*, that star being very near the solstitial colure, so that its changes of declination and of latitude are almost the same. In order to show the truth of his theory, he computed the aberration of different stars, and, on comparing the results with his observations, the coincidence appeared almost perfect, so that no doubt remained concerning the truth of the principle on which he had founded his calculations. He did not explain the rules themselves: Clairaut published the first investigation of these in the *Memoirs of the Academy of Sciences* for 1737. Simpson also gave a demonstration of them in his *Essays*, published in 1740.

It has been remarked, that the velocity of light, as assumed by Bradley, did not exactly agree with that which Römer had assigned; supposing the total amount of the aberration 40½″, it gave the time that light takes to come from the sun to the earth 8′ 13″; but it is proper to add, that since the time of this astronomer, the velocity of light deduced from the eclipses of Jupiter's satellites has been found exactly the same.

It is remarkable that the phenomenon thus discovered by Bradley and Molyneux, when in search of the parallax of the fixed stars, is in reality as convincing a proof of the earth's motion in its orbit, as the discovery of that parallax would have been. It seems, indeed, as satisfactory as any evidence that can be desired. One only regrets in reflecting on this discovery, that the phenomenon of the aberration was not foreseen, and that, after being predicted from theory, it had been ascertained from observation. As the matter stands, however, the discovery both of the fact and the theory is highly creditable to its author.

In the imperfect outline which I have now sketched of one of the most interesting periods in the history of human knowledge, much has been omitted, and many great characters passed over, lost, as it were, in the splendour of the two great luminaries which marked this epocha. Newton and Leibnitz are so distinguished from the rest even of the scientific world, that we can only compare them with one another, though, in fact, no two intellectual characters, who both reached the highest degree of excellence, were ever more dissimilar.

For the variety of his genius, and the extent of his research, Leibnitz is perhaps altogether unrivalled. A lawyer, a historian, an antiquary, a poet, and a philologist,—a mathematician, a metaphysician, a theologian, and I will add a geologer, he has in all these characters produced works of great merit, and in some of them of the highest excellence. It is rare that original genius has so little of a peculiar direction, or is disposed to scatter its efforts over so wide a field. Though a man of great inventive powers, he occupied much of his time in works of mere labour and erudition, where there was nothing to invent, and not much of importance to discover. Of his inventive powers as a mathematician we have already spoken; as a metaphysician, his acuteness and depth are universally admitted; but metaphysics is a science in which there are few discoveries to be made, and the man who searches in it for novelty, is more likely to find what is imaginary than what is real. The notion of the *Monads*, those unextended units, or simple essences, of which, according to this philosopher, all things corporeal and spiritual, material or intellectual, are formed, will be readily allowed to have more in it of novelty than truth. The *pre-*

established harmony between the body and the mind, by which two substances incapable of acting on one another, are so nicely adjusted from the beginning, that their movements for ever correspond, is a system of which no argument can do more than prove the possibility. And, amid all the talent and acuteness with which these doctrines are supported, it seems to argue some unsoundness of understanding, to have thought that they could ever find a place among the established principles of human knowledge.

Newton did not aim at so wide a range. Fortunately for himself and for the world, his genius was more determined to a particular point, and its efforts were more concentrated. Their direction was to the accurate sciences, and they soon proved equally inventive in the pure and in the mixed mathematics. Newton knew how to transfer the truths of abstract science to the study of things actually existing, and, by returning in the opposite direction, to enrich the former by ideas derived from the latter. In experimental and inductive investigation, he was as great as in the pure mathematics, and his discoveries as distinguished in the one as in the other. In this double claim to renown, Newton stands yet unrivalled; and though, in the pure mathematics, equals may perhaps be found, no one, I believe, will come forward as his rival both in that science and in the philosophy of nature. His caution in adopting general principles; his dislike to what was vague or obscure; his rejection of all theories from which precise conclusions cannot be deduced; and his readiness to relinquish those that depart in any degree from the truth, are, throughout, the characters of his philosophy, and distinguish it very essentially from the philosophy of Leibnitz. The characters now enumerated are most of them negative, but without the principles on which they are founded, invention can hardly be kept in the right course. The German philosopher was not furnished with them in the same degree as the English, and hence his great talents have run very frequently to waste.

It may be doubted also, whether Leibnitz's great metaphysical acuteness did not sometimes mislead him in the study of nature, by inclining him to those reasonings which proceed, or affect to proceed, continually from the cause to the effect. The attributes of the Deity were the axioms of his philosophy; and he did not reflect that this foundation, excellent in itself, lies much too deep for a structure that is to be raised by so feeble an architect as man; or, that an argument, which sets out with the most profound respect to the Supreme Being, usually terminates in the most unwarrantable presumption. His reasonings from first causes are always ingenious; but nothing can prevent the substitution of such causes for those that are physical and efficient, from being one of the worst and most fatal errors in philosophy.

As an interpreter of nature, therefore, Leibnitz stands in no comparison with Newton. His general views in physics were vague and unsatisfactory; he had no great value for inductive reasoning; it was not the way of arriving at truth which he was accustomed to take; and hence, to the greatest physical discovery of that age, and that which was established by the most ample induction, the existence of gravity as a *fact* in which all bodies agree, he was always incredulous, because no proof of it, *à priori*, could be given.

As to who benefited human knowledge the most, no question, therefore, can arise; and if genius is to be weighed in this balance, it is evident which scale must preponderate. Except in the pure mathematics, Leibnitz, with all his talents, made no material or permanent addition to the sciences. Newton, to equal inventions in mathematics, added the greatest discoveries in the philosophy of nature; and, in passing through his hands, Mechanics, Optics, and Astronomy, were not merely improved, but renovated. No one ever left knowledge in a state so different from that in which he found it. Men were instructed not only in new truths, but in new methods of discovering truth; they were made acquainted with the great principle which connects together the most distant regions of space, as well as the most remote periods of duration; and which was to lead to future discoveries, far beyond what the wisest or most sanguine could anticipate.

Supplement

TO THE

ENCYCLOPÆDIA BRITANNICA.

EDINBURGH. In the *Encyclopædia* will be found a full account of this City, till the year 1812; and we shall now give a short view of its improvements and increase since that period.

Ever since the year 1769, when the building of the New Town commenced, the improvement of Edinburgh has been prosecuted with extraordinary zeal, both by the magistrates and by the inhabitants, and, of late years more especially, the exertions of all ranks have been directed to this object. In consequence of this general and laudable spirit, the city of Edinburgh has not only been extended on all sides, but has been improved by the addition of some splendid public edifices; while the access to it from every quarter has been greatly facilitated and embellished.

New Streets. In addition to the original streets of the New Town, namely, Prince's Street, George's Street, and Queen's Street, with their respective cross streets, and several other intermediate ones of inferior note, an important extension has been projected, and is now in part executing, on the inclined plane towards the north The plan of these additional streets is nearly similar to that of the original part of the New Town, consisting chiefly of parallel rows of building, into which the improvement of curved streets is tastefully introduced. Part of an interval of unoccupied ground between the old and these new streets, formerly private property, has been purchased, and is now open to the inhabitants of this quarter of the town, for whose convenience it has been tastefully laid out in walks, ornamented with trees; forming a garden view extremely pleasant to the eye from its verdure and beauty. Fronting this space, a very elegant street and crescent have been already built, together with several parallel and retiring streets; and this part of the town continues rapidly to increase. The ground, which, within these four last years, consisted of green fields, is now covered with elegant and spacious streets; other streets are in progress; and new and important additions are in contemplation, by which some of them will be prolonged eastward as far as Leith Walk.

New access from the East. The inconvenience of the access to Edinburgh by the great London road was long a subject of general regret. In entering the city from this quarter, the road lay through narrow and inconvenient streets, forming an approach no way suited to the general elegance of the place. In the year 1814, active measures were at length adopted to remedy this defect. For this purpose, it was proposed to form a magnificent entrance across the Calton Hill, and this plan is now nearly completed. A spacious road, paved at an immense expense, has been carried quite across the hill;—in one part, a passage has been cut through the solid rock, and an immense mass of ground has been levelled, so as to facilitate the ascent. Between the Calton Hill and Prince's Street, a deep ravine intervened, which was formerly occupied with old and ill-built streets. In order to connect the hill with Prince's Street, all these have been swept away, and an elegant bridge of one arch has been thrown over the hollow, which makes the descent from the Hill into this street easy and agreeable. Thus, in place of being carried, as formerly, through long and narrow streets, the great road from the east into Edinburgh sweeps along the side of the singular and steep elevation of the Calton Hill; whence the traveller has first a view of the Old Town, with its elevated buildings crowning the summit of the adjoining ridges, and rising upon the eye in imposing masses; and, afterwards, of the New Town finely contrasted with the Old, in the regularity and elegance of its general outline. The Calton Hill is a singularly striking and romantic object, and in laying it out, there is ample scope for picturesque effect. In the late improvements this has not been neglected. Walks at different elevations have been cut around it, from which is seen, to great advantage, the Old and New Town projected on the plain below; while, at a greater distance, the eye ranges over a wide extent of the adjacent country, viewing in the north and east the Frith of Forth, the high grounds of Fife, and the German Ocean, and towards the south and west, a wide extent of cultivated plains terminated by distant hills.

Plan of Building on the Calton *Hill.*

According to a plan which has been drawn out by Mr. William Playfair, a young architect of the greatest promise, the ground which lies between the Calton Hill and Leith is proposed to be laid out in new streets; and some farther embellishments are to be added to the Hill, for the purpose of making it subservient to the general effect of the intended improvements. On the grand road, which is just begun, and which is to run along the bottom of the Hill on the north, it is proposed to build a large crescent, from which three main streets will diverge towards the town. The northern side of the main road being left partly unbuilt, an excellent situation will be obtained for public buildings; and it is proposed that a building of this description should be erected as an appropriate termination to each of the principal streets just mentioned. Above these public buildings, a handsome row or terrace is to be built, sufficiently elevated to overlook the houses below, and to present an extensive prospect of the more distant country. It is intended that this terrace should sweep round by an easy curve into a long line of building, proposed to be ranged along the side of the Regent Road on the opposite side of the hill; and that the space between this and the Regent Road should be converted into gardens, which, when properly laid out and planted, will become an agreeable and inviting retirement; and will, at the same time, present a pleasing foreground to the delightful scenery which is to be seen from the public walks above. In planning the ground along Leith Walk, it is proposed, in like manner, that squares and incurved streets should be tastefully introduced, that the eye may be relieved from the dull uniformity which is presented by the constant recurrence of the same regular parallels. Besides these improvements, the Eastern Road, which forms one of the great communications with Leith, will be considerably widened, and four rows of trees planted along its whole length, in order to convert it into an agreeable walk for the inhabitants.

This extension of the city is, however, only in contemplation. But there are other improvements equally important which are either already executed or in progress.

Progress of the New College.

The *Encyclopædia* contains an account of the University; and it is stated, that the original structure was partly taken down to make way for one more suited to the taste of modern times, and capable of accommodating the increasing concourse of students which the growing celebrity of this seminary was attracting from all parts. A most magnificent and extensive pile was begun, the funds for which were to be supplied by subscription. But it was soon found, that this work was planned on too extensive a scale, and the money collected being exhausted, the progress of the work was interrupted, and the building remained, in consequence, for a long time in a most awkward and unfinished state, a deformity, in place of an ornament, to the metropolis. By the liberality of Government a grant of public money has been obtained, and the work has been recommenced on a reduced, and it may, perhaps, be added, an improved plan, furnished by Mr. Playfair. According to the original plan of Mr. Adam, the interior space inclosed by the buildings of the University was divided into two courts or areas by a central range of buildings. In the new plan this range of buildings is left out, and the whole interior space is thrown into an open court; and such alterations and additions have been introduced, as were necessary to obviate incongruities, and to give to the whole an aspect of perfect uniformity. The access into the court is through a spacious gateway; and a person entering will have, on the one hand, a view of the buildings containing the library, and on the other those occupied by the rooms for the accommodation of the classes; while opposite to him will be the museum, the front of which is finely ornamented with Corinthian columns, resting on a rusticated arcade.

With respect to its interior arrangements, this edifice is laid out in suitable apartments for the library, the museum, the graduation hall, and chapel, and class rooms for the professors. According to the new plan, the library will be divided into two stories, the lower of which will be separated into five compartments, communicating with each other by folding doors. The anti-room will form a spacious apartment, forty-seven feet long, twenty-four feet wide, and twenty-two feet high, well lighted by a large window from the court. The next apartment is of a circular form, forty feet in diameter and sixty-four feet in height, lighted from the top, and having a gallery running round it. Farther on is the central room, sixty feet long, forty-seven feet wide, and twenty-two feet high, which is intended to be fitted up as a graduation hall and chapel. Beyond this are two rooms to correspond to the circular room and the outer room already described. The upper compartment of the library is on a plan similar to the one below, with this exception, that the central division is thirty feet in height, having an arched ceiling supported by sixteen Corinthian columns. In place, also, of a division into compartments, the whole is thrown into one great room; so that the eye ranges from one extremity to the other, extending to a distance of 190 feet; the circular rooms with their domes, and the centre compartment with its arched ceiling, producing a noble variety, while the columns with their unbroken entablature, will give simplicity and coherence to the whole. The museum for specimens of natural history, the stock of which is daily accumulating, occupies two large rooms in different stories. The lower room is ninety feet long, thirty-four feet wide, and twenty-four feet high. It is proposed to furnish it in a simple and appropriate manner, the ceiling being left quite plain, and supported by Doric columns. The upper apartment is of the same length and breadth as the one below; but is considerably higher as it extends upwards towards the roof. In the middle of it is a dome 22 feet in diameter, the centre of which is occupied by a sky-light, from which and from other points an abundant supply of light is obtained for the exhibition of the specimens.

The rooms appropriated to the different classes are conveniently disposed on the intermediate floors between the pavement floor and the attics. The following is the number of students that have attended the University for the last four years: In 1814, 2029; 1815, 2097; 1816, 2025; 1817, 2024; and in 1818, 2160.

New Libraries.

That large and irregular pile of building in the Parliament Square, in which the Supreme Courts hold their sittings for the administration of justice, has lately received various additions and improvements. In the interior, great reparations have been made, and the front has been replaced by another, with an elegant piazza. Attached to the north-west corner of the Parliament House, magnificent apartments have lately been finished for the reception of the Advocates' Library, and that of the Writers to the Signet. The room appropriated to the latter, which is 105 feet in length, is divided into two parts, by means of open arches, the first of the compartments being oblong, and the second square. The ceiling of the oblong division is supported by two rows of Corinthian columns, which, besides being in themselves highly elegant and ornamental, completely obviate the want of height, which might otherwise have in some degree marred the general appearance of so large a room. On entering the great door, the colonnade continued for seven intercolumniations, without any break or interruption, produces a simple and noble effect, and through the ornamented arches by which this part of the hall is separated from the inner apartment, the latter appears rich and magnificent. Nor is the view from the upper end of the room at all inferior, the colonnade as seen through the arch receding from the eye in regular and beautiful gradation. The room over this is appropriated to the Advocates' Library, and is about 25 feet longer. It is loftier, and more gorgeously ornamented; but the general effect is not so pleasing. Both were executed from designs furnished by the late Mr. William Stark, who has left some other noble monuments of his genius in the public buildings of Glasgow.

New Churches.

Several new churches have been erected in Edinburgh of very elegant architecture. St George's Church, which was opened for divine service in June 1814, presents a front to Charlotte Square of 112 feet, with a portico, supported by four Ionic columns, 35 feet in height, elevated on a flight of steps. A dome, 48 feet square, rises from a basement behind the portico, above which is a circular row of columns, surmounted by the upper compartments of the dome; and the whole is crowned by a lantern, with a cross, 160 feet from the ground. This church is favourably situated for effect, and viewed from particular points, and at a distance, it appears a grand and striking object. It is, however, greatly surpassed in elegance of architecture by the two Episcopal Chapels of St Paul's and St John's, opened for divine service in the year 1818. The chapel of St Paul's is finished in the style of Gothic architecture, which prevailed in the reign of Henry VI., during which period it had reached its greatest perfection. It is 122 feet in length, by 73 feet over the walls, and resembles in its form that of King's College, Cambridge, with this difference, however, that the circles are wider in proportion, and the octagon towers more ornamented. Although this style of architecture is susceptible of the highest decoration, the design of this chapel is remarkable, chiefly for the simplicity and continuity of its parts; and it is in vain that we look for the same striking effect in any of the edifices executed at the commencement, or during the decline of this style of architecture. The building consists of a nave and two side aisles. The interior dimensions are 105 feet by 63 feet; the nave is 105 feet by 26 feet, and 46 feet high; the two aisles are each 79 feet by 13 feet 6 inches, and 29 feet high. The ceiling of the nave is a flat Gothic arch, with ornamented ribs and tracery mouldings. The ceilings over the galleries are ornamented in the same manner, and those under the galleries are decorated with perforated ribs, and head and point ornaments. The altar window, which is 32 feet high, by 13 feet wide, is ornamented with a flaming cross, pendant, amid a wreath of clouds, and the opposite window is set with coloured glass. Over the buttresses of the outer and inner walls are richly carved pinnacles; and on each side of the two principal windows a graceful octagonal tower ascends to the height of 75 feet. This edifice was designed by Mr. Elliot, and the plan and execution reflect great credit on his taste and talents. It was begun in 1816, and finished in 1818, at an expence of L.12,000. The chapel of St John, which stands at the west end of Prince's Street, and which is built from a design by Mr. Burn, architect, is generally regarded as a fine specimen of Gothic architecture. Its form is that of a parallelogram, running east and west, with a projection in front 150 feet. The chapel is 109 feet in length, by 66 in breadth. The east end is embellished with a large window, nearly 30 feet high, which, with the lofty Gothic tower, has a striking effect when seen from a distance. The finishing of the roof, in the interior of the nave, is in the florid Gothic style, similar to Henry the Seventh's Chapel, and is finely softened by the orange-coloured light of the upper windows. There are no galleries to break the continuity of the general appearance, which is at once grand and simple. In addition to those churches, a Roman Catholic chapel has been lately built at the end of York Place, in the purest style of Gothic architecture. An elegant church for an Antiburgher congregation has been erected in Nicolson's Street, in the same style of architecture.

New Observatory. The want of an Observatory was long a subject of regret among the men of science in Edinburgh; and so early as the year 1736, a building of this nature was begun, but, from various causes, it was not prosecuted to a conclusion. In the year 1812, an Astronomical Institution was formed partly for the purpose of remedying this want; and, on the 25th April 1818, the foundation-stone of an Observatory was laid on the Calton Hill, in order, as is expressed on the plate deposited at the foundation, "that a great city, renowned for luxury and knowledge, might no longer be without the means of cultivating the most sublime and most perfect of the sciences." The building, the plan of which was furnished by Mr. Playfair, is in the shape of a cross, formed by four Doric porticoes facing the four quarters of the heavens, and consisting each of six columns elevated upon steps. The interior contains an entrance-hall, with a stair case adjoining, a room for the accommodation of the observer, and the great room for the astronomical instruments, which consist of a transmit instrument, an astronomical circle, and a mural circle. These are to rest on massive stone piers, which are founded on the solid rock, and every precaution is taken to prevent vibration. The roof is intersected by apertures for the mural circle, and for the transit instrument, and a moveable doom is provided for the astronomical circle.

New Prison. The old Tolbooth, which was originally intended for the Parliament of Scotland, and the Courts of Justice, and which, with the buildings connected with it, long remained an encumbrance on the High Street, was taken down in the year 1817; previous to which a new prison was finished on the Calton Hill, in every respect better calculated both for the security and comfort of the prisoners. It is an extensive building, the ground-flour of which is divided into seven compartments, each containing a good day-room and a court-yard, the court-yards meeting at a point, at which is placed a watch-house. Above the watch-house, on a steep hill impending over the prison, is the Governor's house, a most imposing structure, which completely overlooks the several yards. The upper stories of the building are occupied by the night cells of the different prisoners, ranged on both sides of long galleries. An infirmary is attached to the prison, and also a chapel, in which a clergyman is appointed to officiate. The outward aspect of the building is heavy, and serves to impress on the mind of the spectators the gloomy purpose for which it is erected.

Water and Gas-light Companies. Owing to the great extension of Edinburgh, and to the improvements introduced into the interior economy of the houses, the supply of water brought into the city has of late years been found insufficient for the use of its increasing inhabitants; and a great scarcity of this necessary article has been experienced at different times. To remedy this grievance, a joint stock company has been established, with a capital of L.135,000. There are several springs at the distance of about eight miles, in the Pentland Hills, which it is proposed to bring into the city at the estimated expence of L.85,000, to be defrayed by an increased rate of duty on the houses. A company has also been established for lighting the streets and shops with gas. Their capital amounts to L.100,000, and the principal streets and warehouses have already received the full benefit of this improvement.

Leith Docks. At Leith, which is the sea-port of Edinburgh, great improvements have been executed for the accommodation of the increasing trade. In 1800, a magnificent suite of wet docks was planned; and the first of these beautiful basins, 250 yards in length, by 100 in breadth, and sufficient to accommodate 40 ships of 200 tons, was opened in 1806; a second was opened in 1817, and it is intended to have another dock equal in size to the two former, which will be sufficient for the accommodation of frigates. The two docks, already finished, have cost L.250,000.

General Observations. Edinburgh is in no respect a trading or manufacturing town. Being the seat of the supreme Courts of Justice for Scotland, and also of a celebrated university, with other important institutions for education, it is chiefly supported by the numerous retainers of these establishments. Law is the leading profession, and those who are connected with it are divided into different classes, namely, Advocates, who plead before the courts, Writers to the Signet, who form the great body of conveyancers, with certain valuable exclusive privileges, and Writers, a generic name for all those who act as solicitors, whether before the supreme or inferior Courts. A considerable class, also, depends on the university and other seminaries; and the constant residence in Edinburgh of so many persons attached to the learned professions has produced a most favourable influence on the minds and character of the inhabitants, and has given generally to the society of this metropolis a tone and polish not to be found in any mercantile place. Edinburgh is also the resort of rank and fashion, as well as of literature and taste. Many opulent families make it their winter residence, partly for the sake of educating their children, and also for the purpose of introducing them on easy terms into the circles of fashionable society. The manufactures of Edinburgh are chiefly of the finer sort, and such as tend to minister to the immediate wants of a refined and luxurious population. They consist of household furniture, travelling carriages, the construction of musical instruments, &c. There are also manufactures of glass, marble, brass, and iron. Two distilleries are established in the neighbourhood, and Edinburgh has always been noted for excellent ale. The trade of Bookselling and Printing has of late years increased to a great extent, and various periodical and other works have been published, some of which have deservedly attained the most extensive celebrity.

Of these the principal is the *Edinburgh Review*, which circulates quarterly 15,000 copies. There are also two monthly magazines, a Monthly Review, besides eight Newspapers, three published thrice a-week, two twice, and three once a-week. The King's printing office, which has the exclusive right of printing Bibles, annually throws off 100,000 copies. (o.)

Extent.

EDINBURGHSHIRE, or, as it is frequently called, MID-LOTHIAN, the seat of the metropolis of North Britain. It is situated between *55° 39′* and *55° 59′* north latitude, and between 2° 36′ and 3° *33′* longitude west from Greenwich. Its boundaries are the Frith of Forth on the north; Linlithgowshire or West-Lothian on the west; the counties of Haddington or East-Lothian, Berwick, and Roxburgh on the east; and those of Selkirk, Peebles, and Lanark on the south; the length of the whole line, which is very irregular and longest on the south, being about 90 miles. The medium length of the county may be taken at 24 miles, and the breadth 15, the area thus comprising 360 square miles, or, by the latest computation, 354 square miles, or 226,560 English acres, of which 145,000, or 64 acres in a hundred, are in cultivation, and the remainder, or more than a third, hilly, or otherwise comparatively unproductive.

The surface of this county exhibits a great variety of natural scenery, almost everywhere blended and embellished with the labours of taste and opulence. The lower and richer part of it is of a semicircular form, inclining towards the Frith of Forth on the north, and terminating near Mid Calder on the west, and Fala on the south-east, but interrupted by the Pentland Hills, which, rising in the south-west, approach to within five miles of the frith, and thus divide the southern part of this track into two large plains. These hills cover about 40 square miles, and though none of them rise to the height of more than 1700 feet, yet their situation in a flat country, and bleak and barren aspect, render them very prominent objects in the landscape. On the south-east, where the county terminates almost in a point, between Roxburgh and Selkirk shires, and about 15 miles from the sea, there is another mountainous track, called the Morefoot Hills, the highest of which rise to upwards of 1800 feet, and extend over 50 square miles. From the rivulet Gala, which flows through it, this is commonly known by the name of the Gala Water district. Fertile valleys are found among these hills, and many of the hills themselves have been cultivated. With the exception of these two hilly tracks, Edinburghshire may be considered as a low lying country, though not level or flat, the surface being varied by ridges and gentle acclivities, and occasionally by detached hills of moderate elevation, among which Arthur's Seat, in the vicinity of Edinburgh, and the Corstorphine Hills, are the most considerable. The view from these eminences is singularly rich and beautiful, embracing, besides the city itself, a great many gentlemen's seats, with their pleasure grounds, and elegant villas thickly planted in every direction,—with the town and shipping of Leith, and the estuary of the Forth expanding into the ocean on the north and north-east, and the plains and high grounds of Fife beyond,—while the naked and rugged hills to the south form a striking contrast with the highly ornamented landscape into which they protrude.

Climate.

The climate is exceedingly variable, but not subject to extremes. Snow seldom falls before December. From March to June, cold east winds often prevail, sometimes attended by great falls of rain. July and August are warm and pleasant. Partly from the nature of the soil, as well as the climate, the corn crops do not come to maturity so soon as in the south of Scotland by three weeks or a month. The fields, in late seasons, are not all cleared, even near the city, till the end of October. According to a register, kept in its immediate vicinity, for eight years, from 1785 to 1792, inclusive, the average number of rainy days was 175, and the quantity of rain 25.75 inches. The thermometer once in the same period was at 89°, and twice besides above 80°; the lowest point 11°; and the average of the whole period was 46.570.

Waters.

The streams of this county are so inconsiderable as not to be called rivers, but *waters*, a term which in Scotland is employed to denote a stream somewhat larger than a brook or *burn*, and whose bed is never in ordinary seasons altogether dry. Almond water, which rises in the borders of Lanarkshire, separates this county from Linlithgowshire for a great part of its course, and falls into the sea near the village of Cramond, where, at high water, it is navigable by sloops for about a quarter of a mile. The water of *Leith* has its source in the western extremity of the parish of Currie, on the north side of the Pentland Hills, and falls into the sea at Leith, after a course of about 16 miles. It flows in a deeper channel than the former; the banks are, for the most part, beautifully fringed with wood. In no part of the island perhaps is so small a body of water employed with greater effect, there being upwards of seventy mills, the greater number corn mills, on ten miles of its course. The Esk is the most considerable rivulet, and also the most beautiful. It is formed of two others of the same name, called the North Esk and the South Esk. The North Esk rises on the southern side of the Pentland Hills, above Newhall, about 14 miles from Edinburgh, and flows by Pennicuik, Roslin, Hawthornden, Lasswade, and Melville Castle, till it meets with the South Esk below Dalkeith. The South Esk has its source in the Morefoot Hills. On its banks, which are also well wooded and picturesque, stand Arniston, Dalhousie, and Newbattle. Their united streams flow into the sea at Musselburgh. The Tyne, which rises in this county, after a course of five or six miles in a north-east direction, passes into East-Lothian; and the Gala, the only rivulet that flows to the south, rising on the north of the Morefoot Hills, leaves this county after it has proceeded about 10 miles, and falls into the Tweed below Galashiels. The Esks and the Gala contain trout, and salmon are caught in the Esk at Musselburgh; but the quantity of either is not considerable.

Minerals.

Edinburghshire abounds in coal, limestone, and sandstone, or, as it is popularly called, *freestone*.

Coal.

A continued bed of coal extends across the whole county from Carlops, on the confines of Tweeddale or Peebles-shire, in a direction from south-west to north-east, nearly 15 miles in length, and from seven to eight in breadth, on both sides of the North Esk. But it is chiefly towards the lower end of this vale that the coal is wrought, where there are in some places 26 seams, from two to ten feet thick. Some of the seams are horizontal, and others almost perpendicular, from which they are distinguished by the names of *flat* seams and *edge* seams; and it has been remarked, that the position of the coal corresponds in some degree with the surface of the ground, being level in the valley of the North Esk, and inclined to the horizon on the higher grounds at a distance. Coal has been wrought in the parish of Lasswade for upwards of two centuries, where it is still so abundant, that the quantity raised is said to be equal to a sixth part of what is obtained from all the coal works of the county. Limestone is found not only in the same track with the coal, but still farther to the east, and also in the south-west, where coal has not yet been discovered. The great quarry at Gilmerton, in the parish of Libberton, about four miles from Edinburgh, is nearly a mile in length, everywhere open to the light of day, and has the appearance of a long chasm, advancing obliquely to the surface. Like the coal in its neighbourhood, the stone rests in an inclined position, which, when removed, leaves a floor of such a moderate declivity as to be descended by paths among the fragments of rock that have been left. At the bottom there is a pool of water. Overhead is a roof of considerable height, consisting of a bed of solid rock, supported by pillars of limestone. The principal freestone quarries are at Craigleith, in the neighbourhood of the city, from which the six columns in the front of the New College were obtained, and at Hailes, in the parish of Colinton, about three miles to the westward. The stone of the former, from its superior whiteness, has been of late most in request for building, but the latter is still unrivalled for flags and for stairs. A stone similar to that of Craigleith, but easier wrought, is now got at Redhall, also in the parish of Colinton. Mill-stones have been wrought in the parish of Pennicuik. Copper has been found in the parish of Currie and some other places, but not so rich as to pay for working. Iron stone abounds in the coal district, and also along the shore from Leith westwards, and stones for building and paving in every parish of the county. A stone similar to the Chinese *Petunse*, used in the manufacture of porcelain, has been found in the Pentland Hills, and clay, fit for being made into crucibles, in the parish of Duddingstone. There are mineral waters in different parts, none of which are of much celebrity. St. Bernard's Well, to the north-west of the city, rose into some repute a few years ago, chiefly by means of the late Lord Gardenstone, but it is now resorted to rather as the termination of an agreeable walk than for its medicinal properties.

Valuation and Rental.

The valuation of Edinburghshire, which appears to have been taken in 1649, is L.191,054, 3s. 9d. Scots, and in 1811, the real rent of the lands, according to the returns made under the property-tax, was L.277,827, 19s. 1d. Sterling, and of the houses, L.400,004, 5s. 6d. In 1795, the landed property was divided into 542 estates, of which 12 belonged to hospitals and other corporate bodies, of the valued rent of L.10,628, 4s. 5d. Scots, or more than an eighteenth part of the whole. Here, as throughout the rest of Scotland, the land is occupied by tenants on leases for a term of years, excepting the comparatively small portion possessed by the proprietors themselves, or let in grass for the season.

Agriculture

Within a few miles round the city, the cultivation of farms is conducted with a view to the wants of that great market, where potatoes, turnips, and clovers, are found more profitable than corn. The price of these crops, sold on the ground, the purchaser taking upon himself all the expence of carrying them to market, or taking them away for his own consumption, may average about L.20 the Scots acre, (about L.16 the English,) and very fine crops sometimes bring more than L.30. Early potatoes, raised within a mile of the city, have been sold, to the extent of several acres on one farm, at L.50 an acre. The manure for raising these crops is amply supplied by the streets and stables of the city, which sells at 3s. a cubic yard or more, according to its quality and the demand. A few years ago, the street soil was let out to one individual, and brought the city a clear revenue of L.2000 a-year. This kind of manure, the effects of which are not so lasting as those of stable or farm-yard dung, enables the farmers to raise large crops of wheat, and other kinds of corn, after the green crops, upon soils that are not naturally very fertile; but the seeds of all sorts with which it abounds are unfavourable to the cleanness of their fields. Their straw, instead of being consumed or converted into manure on their farms, is carried to the city, and sold at a rate averaging from L.3 to L.5 an acre, or sometimes given to stablers in exchange for their dung. The rent of farms, of from 50 to 100 acres, within a mile of the city, is in some instances so high as L.8 or L.10 an acre. Lime is very little employed as a manure within the circle to which the town dung extends. Beyond this circle, the radius of which may be about five miles, the system of cultivation is nearly the same as we have already described under other Scottish counties.

Woods.

The extent of the natural wood has been estimated at 3000 acres, and of plantations about 14,000, together about one acre in every fourteen.

Horticulture.

In 1812, 400 acres were employed in raising vegetables for the city, within a circuit of five miles, and 100 acres more were under strawberries. Mr. Neill, Secretary to the Horticultural Society, states the produce of the former at L.45, and the rent from L.8 to L.16 an acre. Between 60,000 and 70,000 Scots pints of strawberries (nearly half as many English gallons) are annually sold in Edinburgh, at from 10s. 6d. a pint down to 9d. The produce of an acre is from 800 to 900 pints, thus yielding a return not very different from the garden grounds. There are also several nurseries in the immediate vicinity of the city, some of them equal to any in the United Kingdom for their collection of fruit and forest trees, shrubs, and herbaceous plants, as well as for the arrangement and keeping of the grounds. About 130 acres are employed in this way.

Manufactures, &c.

The manufactures and commerce of this county, exclusive of Edinburgh, and Leith its sea-port, are inconsiderable. None of the three great branches of industry, the woollen, cotton, or linen-manufacture, is carried on here to any extent. Distilleries, paper-mills on both branches of the Esk, iron works at Cramond, potteries and salt-pans at Inveresk, and gunpowder works at Temple, on the South Esk, are the most worthy of notice. From the metropolis of Scotland being situated here, the public roads that pass through it in every direction are kept in the best order, and thus promote its internal trade. A system of railways is now in contemplation from the coal works to the south-east of the city, but with a view to their further extension.

Union Canal.

A communication between Edinburgh and Glasgow is now about to be obtained by means of the Union Canal, a work which promises to be of great utility to this county, and the want of which has long been felt. This canal, which is to be five feet deep, and at the surface 37 feet wide, contracting to 22 feet at the bottom, begins at the Lothian Road, on the west of Edinburgh, and, crossing the Water of Leith at Slateford, passes the villages of Ratho, Broxburn, and Winchburgh, and the towns of Linlithgow and Falkirk, and joins the Forth and Clyde Canal at Lock No. 16, near the village of Camelon, after a course of 30 miles. The principal aqueducts are, one over the Water of Leith, at Slateford, 500 feet long and 50 feet high; and another of 12 arches of 50 feet span, over the river Avon, two miles above Linlithgow Bridge, 835 feet long, and 90 feet in height above the bed of the river. Both of these are to be lined with an iron trough instead of puddle. About 28½ miles from Edinburgh, as the line passes Falkirk, there is to be a tunnel through Prospect Hill, a third of a mile in length. There will be nine locks in all on this canal, close together, about a mile west of Falkirk; and to Glasgow from the point of junction, there are four locks more, on the Forth and Clyde Canal; but it is proposed to carry a branch from the Union up to the summit level of the other canal, by which *four* of the Union locks and the four of the Forth and Clyde, will be saved to vessels going directly from Edinburgh to Glasgow, leaving only *five* locks on that passage. The estimate for the Union Canal was L.240,500, which has been raised in shares of L.50 each; and it is not expected that the expence will be more. It was begun at Edinburgh in March 1818, and in March 1819, 14 miles of the 30 were nearly excavated; the whole, it is hoped, may be finished by September 1821. It has been found, on survey, that it may be continued on the same level through East Lothian, by Dalkeith, Haddington, &c. A lockage of 250 feet would carry it down to Leith. One great object of this work is to facilitate the conveyance of coals to the city from the coal-fields near Falkirk.

Villages.

Besides the capital itself, there is no town of any note in Edinburghshire, but a great many thriving villages. Of these may be mentioned, Mid-Calder, Corstorphine, and Cramond, in the north-west; Pennicuik, Dalkeith, Lasswade, Loanhead, and Gilmerton, in the east and south, and Musselburgh, including the villages of Inveresk and Fisherrow, Portobello and Newhaven, on the Frith of Forth. Portobello is a pleasant village, lately built, and much resorted to for sea-bathing. Hot and cold baths have been constructed there upon a very elegant plan. Edinburgh is plentifully supplied with fish by the *fishwives* (as they are called) of Newhaven and Fisherrow, a singularly active and laborious race, and very acute in their dealings, who bring in the fish on their backs in large *creels* or wicker-baskets, and cry them through the streets of the city. Dalkeith, the most populous of the places we have mentioned, has been long distinguished for its great weekly markets for meal and grain. The agreeable and healthy situation of Musselburgh obtained for it of old the name of the *Montpelier* of Scotland.

Principal Seats.

Among the principal seats are, *Dalkeith House*, Duke of Buccleuch; *Newbattle Abbey*, Marquis of Lothian; *Duddingstone*, Marquis of Abercorn; *Dalmahoy*, Earl of Morton; *Dalhousie Castle*, Earl of Dalhousie; *Melville Castle*, Viscount Melville; *Calder House*, Lord Torphichen; *Arniston*, Lord Chief Baron Dundas; *Pennicuik*, Sir George Clerk, member for the county. There is a curious fossil tree on the south bank of the North Esk, in the grounds of Pennicuik, which has lately attracted some notice. A figure of it is given in the new series of the *Scots Magazine* for December 1818. To the above may be added, the names of some other old families, who have long held estates in the county, viz. Baird, Borthwick, Craig, Dalrymple, Dick, Drummond, Foulis, Hope, Inglis, Law, Little, Nesbit, Scott, Trotter, Watson, Wauchope, and Wilkie.

Population.

Edinburghshire sends two members to Parliament, one for the county and another for the city, the only royal burgh in it. The annexed abstract exhibits the state of the population of the county in 1800 and 1811, which there is reason to believe has increased considerably since the last enumeration.—See Robertson's *Survey of Mid-Lothian*—the *Statistical Account of Scotland*—*Beauties of Scotland*, Vol. I.—Sir John Sinclair's *General Report of Scotland*—and for the history and antiquities of the county, Chalmers's *Caledonia*, Vol. II. (A.)

EDRISI, or ALDRISI, the most eminent of the geographers who have written in the Arabic language. There is no individual of equal eminence over whose life there hangs a deeper veil of mystery, the various parts of it affording rather subjects of controversy to the learned than of precise information to the biographer. The place, and even the country in which he was born, compose the first subject of disputation. Sionita and Hezronita, who published a Latin translation of his work at Paris, make him a Nubian, and gave to their work the title of *Geographia Nubiensis;* the "Nubian Geography." They proceeded upon the expression there used, "The Nile of Egypt, which cuts *our* land." Hartmann was at once led to suspect the correctness of this inference, by observing that Nubia was one of the countries of which Edrisi gives the most meagre and imperfect account. His suspicions were confirmed by learning that Ockley, on examining two manuscripts in the Bodleian library, had found in both "that land," instead of "*our* land." It seems now generally agreed, therefore, that there is no reason to suppose him of Nubian origin. Others have given him an Egyptian one, which seems more probable, yet rests solely upon the erroneous reading above referred to. In 1663, Bochart stated that he had found, in a manuscript of Leo Africanus, that Edrisi was born at Mazara, in Sicily, in 1098. Next year, however, the manuscript was edited by Hottinger, in an Appendix to his work, entitled *Bibliothecarius Quadripartibus*, when it appeared, that the person supposed to be Edrisi was there named Esseriff Essachalli. Esseriff, or Scheriff, is indeed an usual appellation of Edrisi, but it is common to many, and is rather a title than a name. The rest of the name, and the date of birth, are materially different, so that there seems very little reason to doubt that Bochart was here mistaken.

The most positive statement on the subject is that of Casiri, who says (*Bibliotheca Arabico-Hispanica*, II. 9.) that if Edrisi, as appeared probable, were the person designated by the Mahommedan writers under the long appellation of Abu Abdallah Mohamad Ben Mohamad Ben Abdallah, Ben Edris, he was born at Septa (Ceuta) on the coast of Morocco, in the year of the Hegira 493 (A.D. 1099). Casiri not only qualifies his statement with this condition, but he does not state the authorities from which it is derived; so that it rests only upon the confidence reposed in his learning and accuracy. Edrisi was long a mighty name in Northern Africa; but, in 919, the dynasty was subverted by Mahedi Abdallah, and the proscribed wrecks of the family, according to D'Herbelot, sought refuge in Sicily. This, certainly, tends to strengthen the Sicilian origin of our author; though it is probable that many would seek refuge by concealment in their native county.

If we may trust the information of Casiri, Edrisi pursued his studies at Cordova, then equally famed as a seat of Moorish empire and a seminary of Arabic learning. From the accurate and particular description he has given of Spain, it is probable that he travelled through a great part of that country. Various circumstances prove that he removed to Sicily, and began to compose his great work under the patronage, and indeed at the express desire, of Roger II. king of that island. It was completed about the year 1153. (Heg. 548.)

It has been a subject of pretty warm controversy among the learned, whether Edrisi was a Mahometan or Christian. Sionita, who adopts the latter opinion, observes that he repeatedly calls our Saviour the Lord Jesus, and on one occasion simply "the Lord," a title which is said never to be applied by Mahometans unless to Mahomet, while they merely say "Jesus, to whom be peace," or "Jesus, to whom be safety." He also speaks with profound respect of the holy Virgin, and of various saints, using, in regard to the latter, the Italian expression instead of the Arabic. These arguments are strenuously repelled by Hartmann, though not, as appears to us, on very solid grounds. He justly remarks, indeed, that the Mahometans speak always with the highest respect of every thing connected with the origin of Christianity. But though this may impair the force of Sionita's arguments, there seems nothing of any importance to place in the opposite scale. Hartmann lays much stress on the circumstance that Edrisi, among his numerous names, bears that of Mahomed, which he says was never born by any Christian; but, though this may imply that he was a Mahometan by birth, it does not authorize us to infer that he may not have become a convert to the opposite faith. He evidently wishes to offend persons of neither profession, and thus writes in a style from which no positive inference can be drawn. But, considering how high religious differences ran in that age, it does not appear very probable that he could have resided in Sicily, or been in such high favour with Roger, without adopting the religion of the monarch and country.

The only thing relative to the life of this eminent author which remains even a subject of controversy, is the period of its termination. Bochart has fixed it in the year 1122; but this date clearly proves that he had some quite different person in view; since it appears, by the preface to Edrisi's own work, that its completion took place in the year 1153. No other notice, or even conjecture, relative to the time or manner of his death, is to be found in any author.

From these meagre notices respecting the life of Edrisi, we shall proceed to give some account of his work. It has appeared under various titles. The first and fullest appears to have been, *The going out of a Curious Man to explore the Regions of the Globe, its Provinces, Islands, Cities, and their Dimensions and Situation.* This is sometimes abbreviated into *The going out of a Curious man to explore the Regions of the Globe;* and sometimes merely *The going out of a Curious Man.* Sionita published it under the name of *Relaxation of the Curious Mind;* but the title of *Nubian Geography,* which he and his companion imposed upon it, though it has become general in Europe, is, as is already observed, altogether arbitrary.

The work contains a full description of the whole world, so far as known to the author, with its countries, cities, and all its features, physical and political. These are arranged, not according to any of the methods to which we are accustomed, but in a manner peculiar to itself. The world is divided into seven *climates,* commencing at the equinoctial line, and extending northwards to the limit at which the earth is supposed to be rendered uninhabitable by cold. Each climate is then divided, by perpendicular lines, into eleven equal parts, beginning with the western coast of Africa, and ending with the eastern coast of Asia. The whole world is thus formed into seventy-seven equal square compartments, resembling those upon a chess-board, or those formed upon a plane map, by the intersecting lines of latitude and longitude. The geographer begins with the first part of the first climate, including the western part of central Africa, and proceeds eastward through the different divisions of this climate, till he finds its termination in the sea of China. He then returns to the first part of the second climate, and so proceeds till he reaches the eleventh part of the seventh climate, which terminates in the north-eastern extremity of Asia. The inconveniences of such an arrangement must be abundantly obvious. Instead of each country, or at least each region of similar physical character, being described by itself, it is severed, by these mechanical sections, into fragments, which are described in different and distant parts of the work; and no connected view is given of any great country.

In drawing the general outlines of cosmography, Edrisi describes the earth as globular; that figure being only interrupted by the varieties of mountains and valleys on its surface. He adheres to the doctrine of those ancient schools, which supposed an uninhabited torrid zone; but, as his knowledge extended to populous countries south of the tropic, he placed the commencement of this zone, with very little propriety, at the equinoctial line: beyond this he says there are neither plants nor animals, all being uninhabitable on account of the heat. Again, the habitable world extends only to the 64th degree of north latitude, beyond which all is frozen with ice and perpetual winter. The circumference of the earth he estimates at 132,000,000 cubits, or 11,000 leagues. He mentions also a measurement by Hermes, which made it 36,000 miles. He divides the whole, according to the established system, into 360 degrees; observing, however, that in consequence of the impossibility of passing the equinoctial line, the known world consists only of one hemisphere: of this one half is land, and the other sea, which last consists chiefly of the great ambient sea, surrounding the earth in a continued circuit, like a zone, and in which "the earth floats like an egg in a basin of water." The only portion of it concerning which much was known was the Atlantic Ocean, called the "Sea of Darkness;" the mind, by a natural process, transferring the obscurity of its own ideas to the object on which they were exercised. That still less known part which rolled along the north eastern extremity of Asia was, from the same principle, called the "Sea of Pitchy Darkness." Besides this great sea, Edrisi reckons seven smaller ones,—the Indian Sea; the Red Sea, or Arabian Gulf; the Green Sea, or the Persian Gulf; the Sea of Damascus, or the Mediterranean; the Sea of the Venetians, or the Adriatic; the Sea of Pontus, or the Black Sea; the Sea of Georgian, or Dailem, by which he means the Caspian.

The countries best known to Edrisi are those of Northern Africa, Spain, and Arabia, which are described with minute topographical exactness. As we possess accounts of them, however, equally detailed, and more recent, the chief value is attached to that part of his work where he treats of the interior parts of Africa; regions into which, notwithstanding immense efforts, no European traveller has yet been able to penetrate. In consequence of the colonies and settlements formed there by several Arabian dynasties, Edrisi possessed opportunities of information, of which religious estrangement has deprived Christian Europe. His description, however, cannot be considered as throughout correct; or rather, it is so only for a certain space; after which it deviates into the realms of imagination and conjecture. The leading feature delineated by him is that of the great central river, called the *Nile of the Negroes,* the Niger of Ptolemy and of the moderns, which he represents to rise from the same fountain as the Egyptian Nile, and to flow westwards till it falls into the sea. This statement has not been confirmed by modern discovery, but it is doubtful how far the moderns may not have erred as to the regions designated by Edrisi, and even the precise import of the terms employed by him. From him, however, have been delineated, in all our modern maps, Wangara, surrounded by the branches of the Niger, which form in it two large lakes; with the cities of Gana, Tocrur, Berissa, and Sala, situated along its banks. The eastern coast of Africa is described accurately as to the countries contained in it, but with a singular error of direction, being made to run from west to east, parallel to the southern coast of Asia. The idea was probably suggested by the great unknown continent of Ptolemy, which was made to follow the same direction; and it was rendered almost necessary by our author's hypothesis, that no country could be habitable to the south of the line; since such an extent of coast produced in a southerly direction must necessarily have passed that limit. Thus, however, Sofala is placed upon the sea of China, while Madagascar, under the name of Al Comr, or the Island of the Moon, forms part of the oriental archipelago. In Asia, Edrisi shows considerable acquaintance with the central and southern regions, though he has not described them so fully as Abulfeda and other writers, who resided in Syria and Bagdad. The northern part is occupied by the fabulous abodes of Yagiouje and Magiouje, or Gog and Magog. Their territories were defended by a tremendous castle or rampart of iron, the idea of which was probably derived from some fortified pass in the mountains which stretch across central Asia.

In Europe, with the exception of Spain and Sicily, the information of Edrisi is neither accurate nor extensive. Germany is particularly ill delineated; England he describes as a great Island, in its form resembling an ostrich, in which are seen "cities, lofty mountains, flowing rivers, and a level land, but where perpetual winter reigns." He names its capital and principal sea-ports. To the north is the *island* of Scotland, some features of which he mentions, though in a manner difficult to identify. He mentions also Ireland, and appears even to have a faint knowledge of Orkney and Shetland.

The only valuable unpublished manuscripts of Edrisi which now exist in Europe, are two that are preserved in the Bodleian Library. The first, which was brought over by Greaves from Egypt, is written in the Arabic character peculiar to northern Africa. It is illustrated by a map of the known world, and by thirty-three maps, containing each part of a climate, so that there are maps only for the three first climates. The second manuscript, brought by Pococke from Syria, is written in the Arabic character, as used in that country, and bears the date of 906. Heg. (A. D. 1500). It consists of 320 leaves, and is illustrated by one general and seventy-seven particular maps, the last consequently including all the parts of every climate. The general map has been published by Dr. Vincent in his *Periplus of the Egyptian Sea.* The writer of this article has examined these maps, and found them to throw considerable light upon the geographical system adopted by the Arabian writers.

There is a manuscript (Cod. DLXXX) in the Royal Library at Paris, which professes to be the production of Edrisi; but D'Herbelot, it appears, has not made use of it as such; and De Guignes expresses positive disbelief on the subject. Hartmann, however, found it to coincide, in many particulars, with the geography of Edrisi. A copy of our author's work was contained, at one time, in the library of the Escurial, but it was destroyed by a great fire in 1671.

The geography of Edrisi, in the original Arabic, was printed at Rome in 1592, at the Medicean press, from a manuscript preserved in the Grand-ducal library at Florence. Both the paper and printing are exceedingly neat; the latter being made to resemble manuscript. This unfortunately constitutes the whole merit of the edition, which swarms with typographical errors, and forms, besides, only an epitome of the original work. This epitome seems made, indeed, in the oriental style, by the simple omission of those parts which appeared to the editor to be superfluous; but these comprise many essential and important passages. The description of Mecca, for example, which had been unaccountably omitted, is supplied by Pococke from his manuscript. Hartmann gives instances, where reference is made to the description of places of which there occurs no other mention. D'Herbelot and Casiri equally remark the imperfections of this edition; and the information obtained by the writer of this article at Oxford as to the result of a comparison between it and the manuscripts in that university, tends entirely to confirm their statements. In most bibliographical works, this impression has been characterised as one of the rarest of books; but Adler, in a visit to Florence, found, in the palace there, 1129 copies, which were publicly exposed to sale at a moderate rate. If, therefore, the book be wanting, even in many extensive public libraries, it is merely because those libraries have not taken the trouble to procure it.

In 1619, two oriental scholars, Gabriel Sionita and John Hezronita, published at Paris a Latin translation of Edrisi's work, bearing the title, as already observed, of *Geographia Nubiensis.* It is not executed with all that care and accuracy which might have been expected from these learned personages. They have been particularly careless as to the proper names, which are given sometimes in Latin, sometimes in Arabic, sometimes in neither, nor in any intelligible language. In consequence of the Arabic original being occasionally appended, it has been supposed to have been reprinted along with it; but this is a mistake, there being no edition ever printed except the Roman one. George Hieronymus Velschius, an eminent German scholar, had prepared a copy of the Arabic original, with a Latin translation, which he intended to have illustrated with notes; but death prevented the execution of this design; and his manuscript remains deposited in the library of the University of Jena. Casiri (*Bibliotheca Arab. Hispan.* II. 13.) mentions that, at the request of many friends, he had determined to re-edit this work, but he never appears to have executed this intention. The part relating to Africa, pre-eminent, certainly, in point of importance, has been very ably edited by Hartmann, Professor of Oriental Languages at Marburg (Edrisi, *Africa,* Gottingen, 1796). Instead of following the awkward division into climates, he has collected together all the notices relating to each particular country; and has annexed the statements of the countrymen and contemporaries of Edrisi, so that his work forms nearly a complete body of Arabian geography, so far as relates to Africa. It does not appear, however, that he had an opportunity of consulting the

Oxford manuscripts, or any others of importance, by which the deficiencies of the printed edition could be supplied. A complete edition of this work is, therefore, still wanting; and the learned world may naturally expect it from the University of Oxford, which possesses, in Mr. Nicol, Junior Librarian of the Bodleian, a scholar well qualified for the task, and who promises to support the long-established fame of the University in oriental literature. (B.)

EDUCATION.

The end of education is to render the individual, as much as possible, an instrument of happiness, first to himself, and next to other beings.

The properties, by which he is fitted to become an instrument to this end, are, partly, those of the body, and, partly, those of the mind.

Happiness depends upon the condition of the Body, either immediately, as where the bodily powers are exerted for the attainment of some good; or mediately, through the mind, as where the condition of the body affects the qualities of the mind.

Education, in the sense in which it is usually taken, and in which it shall here be used, denotes the means which may be employed to render the *mind*, as far as possible, an operative cause of happiness. The mode in which the *body* may be rendered the most fit for operating as an instrument of happiness is generally considered as a different species of inquiry, and is thought to belong to physicians and others, who study the means of perfecting the bodily powers.

Definition.

Education, then, in the sense in which we are now receiving it, may be defined, the best employment of all the means which can be made use of, by man, for rendering the human mind to the greatest possible degree the cause of human happiness. Every thing, therefore, which operates, from the first germ of existence, to the final extinction of life, in such a manner as to affect those qualities of the mind on which happiness in any degree depends, comes within the scope of the present inquiry. The grand question of education embraces nothing less than this—namely, What can be done by the human powers, by aid of all the means which are at human disposal, to render the human mind the instrument of the greatest degree of happiness? It is evident, therefore, that nothing, of any kind, which operates at any period of life, however early, or however late, ought to be left out of the account. Happiness is too precious an effect, to let any cause of it, however small, run to waste and be lost. The means of human happiness are not so numerous that any of them can be spared. Not to turn every thing to account, is here, if any where, bad economy, in the most emphatical sense of the phrase.

Objects of this Article.

The field, it will easily be seen, is exceedingly comprehensive. It is everywhere, among enlightened men, a subject of the deepest complaint, that the business of education is ill performed; and that, in this, which might have been supposed the most interesting of all human concerns, the practical proceedings remain far behind the actual state of the human mind. It may be remarked, that, notwithstanding all that has been written on the subject, even the *theory* of education has not kept pace with the progress of philosophy; and it is unhappily true, that the *practice* remains to a prodigious distance behind the theory. One reason why the theory, or the combination of ideas which the present state of knowledge might afford for improving the business of education, remains so imperfect, probably is, that the writers have taken but a partial view of the subject; in other words, the greater number have mistaken a part of it for the whole. And another reason of not less importance is, that they have generally contented themselves with vague ideas of the object or end to which education is only useful as means. One grand purpose of the present inquiry will be to obviate all these mistakes; and, if not to exhibit that comprehensive view, which we think is desirable, but to which our limits are wholly inadequate; at any rate, to conduct the reader into that train of thought which will lead him to observe for himself the ultimate boundaries of the field; and, conceiving more accurately the end, to form a better estimate of what is desirable as the means.

Division of these objects.

1. It has been remarked, that every thing, from the first germ of existence to the final extinction of life, which operates in such a manner as to affect those qualities of the mind on which happiness in any degree depends, comes within the scope of the present inquiry. Those circumstances may be all, according to the hackneyed division, arranged under two heads: They are either Physical or Moral; meaning by Physical, those of a material nature, which operate more immediately upon the material part of the frame; by Moral, those of a mental nature, which operate more immediately upon the mental part of the frame. What are those physical and moral circumstances which may be made to operate upon the mind in such a manner as to render it a better instrument or cause of happiness, is, therefore, one object of the present inquiry.

2. In order to know in what manner things operate upon the mind, it is necessary to know how the mind is constructed. *Quicquid recipitur, recipitur ad modum recipientis.* This is the old aphorism, and no where more applicable than to the present case. If you attempt to act upon the mind, in ways not adapted to its nature, the least evil you incur is to lose your labour.

3. As happiness is the end, and the means ought to be nicely adapted to the end, it is necessary to inquire, What are the qualities of mind which chiefly conduce to happiness,—both the happiness of the individual himself, and the happiness of his fellow creatures?

It appears to us, that this distribution includes the whole of the subject. Each of these divisions branches itself out into a great number of inquiries. And, it is manifest, that the complete developement of any one of them would require a greater space than we can allow for the whole. It is, therefore, necessary for us, if we aim at a comprehensive view, to confine ourselves to a skeleton; and this we think is both the most instructive course we can pursue, and the best adapted to the nature of the work for which it is designed.

Order of inquiry.

The next question is, Which of these three divisions of the inquiry it will be most advantageous to the developement of the subject to begin with. The first, it is evident, is the most practical, and, therefore, likely to be the most interesting. Under the Physical Head, it includes inquiries into the mode in which the qualities of the mind are affected by the health, the aliment, the air, the labour, &c. to which the individual is subject. Under the Moral Head it includes inquiries into what may be called, 1. Domestic education, or the mode in which the mind of the individual is liable to be formed by the conduct of the individuals composing the family in which he is born and bred: 2. Technical or scholastic education, including all those exercises upon which the individual is put, as means to the acquisition of habits,—habits either conducive to intellectual and moral excellence, or even to the practice of the manual arts: 3. Social education, or the mode in which the mind of the individual is liable to be affected by the conduct of the men who form the society in which he moves: 4. Political education, or the mode in which the mind of the individual is acted upon by the nature of the political institutions under which he lives.

The two latter divisions comprehend what is more purely theoretical; and the discussion of them will, therefore, have fewer attractions to that class of readers, unhappily numerous, to whom intellectual exercises have not by habit been rendered delightful. To the inquiries, however, which are included under the first division, it appears, that those included under the two last are required as a foundation. The fact is, that good practice can, in no case, have any solid foundation but in sound theory. This is not more important, than it is demonstrable and certain. For, What is theory? It is the putting the *whole* of the knowledge, which we possess upon any subject, into that order and form in which it is most easy to draw from it good practical rules. Let any one examine this definition, article by article, and show us that it fails in a single particular. If it does not, let us no longer hear of the separation of theory from practice.

Nature of the Mind, as connected with Educc.

1. The first, then, of the inquiries, embraced by the great subject of education, is that which regards the nature of the human mind: and the business is, agreeably to the foregoing definition of theory, to put the knowledge which we possess respecting the human mind, into that order and form, which is most advantageous for drawing from it the practical rules of education. The question is, How the mind, with those properties which it possesses, can, through the operation of certain means, be rendered most conducive to a certain end? To answer this question, the whole of its properties must be known. The whole science of human nature is, therefore, but a branch of the science of education. Nor can education assume its most perfect form, till the science of the human mind has reached its highest point of improvement. Even an outline, however, of the philosophy of the human mind would exceed the proportion of the present article; we must, therefore, show what ought to be done, rather than attempt, in any degree, to execute so extensive a project.

With respect to the human mind, as with respect to every thing else, all that passes with us, under the name of knowledge, is either matter of experience, or, to carry on the analogy of expression, matter of guess. The first is real knowledge: the properties of the object correspond to it. The latter is supposititious knowledge, and the properties of the object do or do not correspond to it; most likely not. The first thing desirable is, to make an exact separation of those two kinds of knowledge; and, as much as possible, to confine ourselves to the first.

What, then, is it which we experience with regard to the human mind? and what is it which we guess? We have experience of ourselves, when we *see*, when we *hear*, when we *taste*, when we *imagine*. when we *fear*, when we *love*, when we *desire*; and so on. And we give names, as above, to distinguish what we experience of ourselves, on one of those occasions, from what we experience on another. We have experience of other men exhibiting *signs* of having similar experiences of themselves, that is, of *seeing*, *hearing*, and so on. It is necessary to explain, shortly, what is here meant by a sign. When we ourselves *see*, *hear*, *imagine*, &c. certain actions of ours commonly follow. We know, accordingly, that if any one, observing those actions, were to infer that we had been *seeing*, *hearing*, &c., the inference would be just. As often then as we observe similar actions in other men, we infer that they, too, have been seeing or hearing; and we thus regard the action as the sign.

Having got names to distinguish the state or experience of ourselves, when we say, *I see*, *I hear*, *I wish*, and so on; we find occasion for a name which will distinguish the having of any (be it what it may) of those experiences, from the being altogether without them; and, for this purpose, we say, *I feel*, which will apply, generally, to any of the cases in which we say, *I see*, or *hear*, or *remember*, or *fear*; and comprehends the meaning of them all. The term *I think*, is commonly used for a purpose nearly the same. But it is not quite so comprehensive. There are several things which we should undoubtedly include under the term *our experience of our mind*, to which we should not extend the term *I think*. But there is nothing whatsoever included under it to which we should not extend the term *I feel*; this is truly, therefore, the generic term.

All our experience, then, of the human mind, is confined to the several occasions on which the term *I feel* can be applied. And, now, What does all this experience amount to? What is the knowledge which it affords? It is, first, a knowl of the *feelings* themselves; we can remember what, one by one, they were. It is, next, a knowledge of the order in which they follow one another; and this is all. But this description, though a just one, is so very general as to be little instructive. It is not easy, however, to speak about those feelings minutely and correctly; because the language which we must apply to them is ill adapted to the purpose.

Let us advert to the first branch of that knowledge, the knowledge of the feelings themselves. This, in the simple cases, may be regarded as easy; the feeling is distinct at the moment of experience, and is distinctly remembered afterwards. But the difficulty is great with the complex cases. It is found, that a great number of simple feelings are apt to become so closely united, as often to assume the appearance of only one feeling, and to render it extremely difficult to distinguish from one another the simple feelings of which it is composed. And one of the grand questions which divide the mental philosophers of the present day, is to determine which feelings are simple, and which are complex. There are two sorts which have, by all, been regarded as simple: Those which we have when we say, I hear, I see, I feel, I taste, I smell, corresponding to the five senses, and which Mr. Hume distinguished by the name of *impressions;* and the feelings corresponding to these impressions, which Mr. Hume calls *ideas* of them; the second taking place only in consequence of the first, and being, as it were, a revival of them; not the same feelings with the impressions, by any means; but feelings which bear a certain resemblance to them. Thus, when a man sees the light of noon, the feeling he has is called an *impression,*—the impression of light; when he shuts his eyes and has a feeling,—the type or relict of the impression,—he is not said to *see* the light, or to have the *impression* of light, but to *conceive* the light, or have an *idea* of it.

These two,—*impressions,* and their correspondent *ideas,*—are simple feelings, in the opinion of all philosophers. But there is one set of philosophers who think that these are the only simple feelings, and that all the rest are merely combinations of them. There is another class of philosophers who think that there are original feelings beside impressions and ideas; as those which correspond to the words *remember, believe, judge, space, time,* &c. Of the first are Hartley and his followers in England, Condillac and his followers in France; of the second description are Dr. Reid and his followers in this country, Kant and the German school of metaphysicians in general on the Continent.

It is evident, that the determination of this question with regard to the first branch of knowledge, namely, what the feelings are? is of very great importance with regard to the second branch of knowledge, namely, what is the order in which those feelings succeed one another? For how can it be known how they succeed one another, if we are ignorant which of them enter into those several groups which form the component parts of the train? It is of vast importance, then, for the business of education, that the analysis of mind should be accurately performed; in other words, that all our complex feelings should be accurately resolved into the simple ones of which they are composed. This, too, is of absolute necessity for the accurate use of language; as the greater number of words are employed to denote those groups of simple feelings which we call complex ideas.

In regard to all the events in this world, of which feelings are a class, our knowledge extends not beyond two points. The first is, a knowledge of the events themselves; the second is, a knowledge of the order of their succession. The expression in words of the first kind of knowledge is history; the expression of the second is philosophy; and to render that expression short and clear is the ultimate aim of philosophy.

The first steps in ascertaining the order of succession among events are familiar and easy. One occurs, and then another, and after that a third, and so on; but at first it is uncertain whether this order is not merely accidental, and such as may never recur. After a time it is observed, that events, similar to those which have already occurred, are occurring again and again. It is next observed, that they are always followed, too, by the same sort of events by which those events were followed to which they are similar; that these second events are followed, in the third place, by events exactly similar to those which followed the events which they resemble; and that there is, thus, an endless round of the same sequences.

If the order in which one event follows another were always different, we would know events only one by one, and they would be infinitely too numerous to receive names. If we could observe none but very short sequences, if, for example, we could ascertain that one event was, indeed, always followed by one other of the same description, but could not trace any constancy farther, we should thus know events by sequences of twos and twos. But those sequences would also be a great deal too numerous to receive names.

The history of the human mind informs us, that the sequences which men first observe are but short ones. They are still, therefore, too numerous to receive names. But men compound the matter. They give names to those sequences which they are most interested in observing, and leave the rest unnamed. They then, when they have occasion to speak of the unnamed successions, apply to them, the best way they can, the names which they have got; endeavouring to make a partial naming answer an universal purpose, and hence almost all the confusion of language and of thought arises.

The great object is, then, to ascertain sequences more and more extensive, till, at last, the succession of all events may be reduced to a number of sequences sufficiently small for each of them to receive a name; and then, and then only, shall we be able to speak wholly free from confusion.

Language affords an instructive example of this mode of ascertaining sequences. In language, the words are the events. When an ignorant man first hears another speak an unknown language, he hears the sounds one by one, but observes no sequence. At last he gathers a knowledge of the use of a few words, and then he has observed a few sequences; and so he goes on till he understands whatever he hears. The sequences, however, which he has observed, are of no greater extent than is necessary to understand the meaning of the speaker; they are, by consequence, very numerous and confusing.

Next comes the grammarian; and he, by dividing the words into different kinds, observes that these kinds follow one another in a certain order, and thus ascertains more enlarged sequences, which, by consequence, reduces their number.

Nor is this all; it is afterwards observed, that words consist, some of one syllable, and some of more than one; that all language may thus be resolved into syllables, and that syllables are much less in number than words; that, therefore, the number of sequences in which they can be formed are less in number, and, by consequence, are more extensive. This is another step in tracing to the most comprehensive sequences the order of succession in that class of events wherein language consists.

It is afterwards observed, that these syllables themselves are compounded; and it is at last found, that they may all be resolved into a small number of elementary sounds corresponding to the simple letters. All language is then found to consist of a limited number of sequences, made up of the different combinations of a few letters.

It is not pretended that the example of language is exactly parallel to the case which it is brought to illustrate. It is sufficient if it aids the reader in seizing the idea meant to be conveyed. It presents, at any rate, a striking analogy between the analysing of a complex sound, namely, a word, into the simple sounds of which it is composed, to wit, letters; and the analysing of a complex feeling, such as the idea of a rose, into the simple feelings of sight, of touch, of taste, of smell, of which the complex idea or feeling is made up. It affords, also, a brilliant proof of the commanding knowledge which is attained of a train of events, by observing the sequences which are formed of the simplest elements into which they can be resolved; and it thus illustrates the two grand operations, by successful perseverance in which the knowledge of the human mind is to be perfected.

It is upon a knowledge of the sequences which take place in the human feelings or thoughts, that the structure of education must be reared. And, though much undoubtedly remains to be cleared up, enough is already known of those sequences to disgrace the education with which our supineness, and love of things as they are, rest perfectly satisfied.

As the happiness, which is the end of education, depends upon the actions of the individual, and as all the actions of man are produced by his feelings or thoughts, the business of education is, to make certain feelings or thoughts take place instead of others. The business of education, then, is to work upon the mental successions. As the sequences among the letters or simple elements of speech, may be made to assume, all the differences between nonsense and the most sublime philosophy, so the sequences, in the feelings which constitute human thought, may assume all the differences between the extremes of madness and of wickedness, and the greatest attainable heights of wisdom and virtue; and almost the whole of this is the effect of education. That, at least, all the difference which exists between classes or bodies of men is the effect of education, without entering into the dispute about individual distinctions, we suppose, will be readily granted; that it is education wholly which constitutes the remarkable difference between the Turk and the Englishman, and even the still more remarkable difference between the most cultivated European and the wildest savage. Whatever is made of any *class* of men, we may then be sure is possible to be made of the whole human race. What a field for exertion! What a prize to be won!

Mr. Hobbes, who saw so much farther into the texture of human thought than all who had gone before him, was the first man, as far as we remember, who pointed out what is peculiarly *knowledge*, in this respect (namely, the order in which our feelings succeed one another)—as a distinct object of study. He marked, with sufficient clearness, the existence and cause of the sequences; but, after a very slight attempt to trace them, he diverged to other inquiries, which had this but indirectly for their object.

"The succession," he says (*Human Nature*, ch. iv.), "of conceptions in the mind, series or consequence (by *consequence* he means *sequence*) of one after another, may be casual and incoherent, as in dreams, for the most part; and it may be orderly, as when the former thought introduceth the latter. The cause of the coherence or consequence (*sequence*) of one conception to another, is their first coherence or consequence at that time when they are produced by sense; as, for example, from St. Andrew the mind runneth to St. Peter, because their names are read together; from St. Peter to a stone, for the same cause; from stone to foundation, because we see them together; and, according to this example, the mind may run almost from any thing to any thing. But, as in the sense, the conception of cause and effect may succeed one another, so may they, *after* sense, in the imagination." By the succession in the *imagination* it is evident he means the succession of *ideas*, as by the succession in *sense*, he means the succession of impressions.

Having said that the conceptions of *cause* and *effect* may succeed one another in the sense, and after sense in the imagination, he adds, "And, for the most part, they do so; the cause whereof is the appetite of them who, having a conception of the *end*, have next unto it a conception of the next *means* to that end; as when a man, from a thought of honour, to which he hath an appetite, cometh to the thought of wisdom, which is the next means thereunto; and from thence to the thought of study, which is the next means to wisdom." (Ib.) Here is a declaration with respect to three grand laws in the sequence of our thoughts. The first is, that the succession of ideas follows the same order which takes place in that of the impressions. The second is, that the order of cause and effect is the most common order in the successions in the imagination, that is, in the succession of ideas. And the third is, that the appetites of individuals have a great power over the successions of ideas; as the thought of the object which the individual desires leads him to the thought of that by which he may attain it.

Mr. Locke took notice of the sequence in the train of ideas, or the order in which they follow one another, only for a particular purpose,—to explain the intellectual singularities which distinguish particular men. "Some of our ideas," he says, "have a natural correspondence and connection one with another. It is the office and excellence of our reason to trace these, and hold them together in that union and correspondence which is founded in their peculiar beings. Besides this, there is another connection of ideas, wholly owing to chance or custom; ideas that are not at all of kin come to be so united in some men's minds, that it is very hard to separate them; they always keep in company, and the one no sooner at any time comes into the understanding, but its associate appears with it; and, if they are more than two which are thus united, the whole gang, always inseparable, show themselves together." There is no attempt here to trace the order of sequence, or to ascertain which antecedents are followed by which consequents; and the accidental, rather than the more general phenomena, are those which seem particularly to have struck his attention. He gave, however, a name to the matter of fact. When one idea is regularly followed by another, he called this constancy of conjunction *the association of the ideas*; and this is the name by which, since the time of Locke, it has been commonly distinguished.

Mr. Hume perceived, much more distinctly than any of the philosophers who had gone before him, that to philosophize concerning the human mind was to trace the order of succession among the elementary feelings of the man. He pointed out three great laws or comprehensive sequences, which he thought included the whole. Ideas followed one another, he said, according to *resemblance*, *contiguity* in time or place, and *cause and effect*. The last of these, the sequence according to cause and effect, was very distinctly conceived, and even the cause of it explained, by Mr. Hobbes. That of contiguity in time and place, is thus satisfactorily explained by Mr. Hume. "It is evident," he says, "that as the senses, in changing their objects, are necessitated to change them regularly, and take them as they lie contiguous to each other, the imagination must, by long custom, acquire the same method of thinking, and run along the parts of space and time in conceiving its objects." (*Treatise of Human Nature*, P. I. B. 1. sect. 4.) This is a reference to one of the laws pointed out by Hobbes, namely, that the order of succession among the ideas follows the order that took place among the impressions. Mr. Hume shows that the order of sense is much governed by contiguity, and why; and assigns this as a sufficient reason of the order which takes place in the imagination. Of the next sequence, that according to resemblance, he gives no account, and only appeals to the consciousness of his reader for the existence of the fact. Mr. Hume farther remarked, that what are called our complex ideas, are only a particular class of cases belonging to the same law, the law of the succession of ideas; every complex idea being only a certain number of simple ideas, which succeed each other so rapidly, as not to be separately distinguishable without an effort of thought. This was a great discovery; but it must at the same time be owned, that it was very imperfectly developed by Mr. Hume. That philosopher proceeded, by aid of these principles, to account for the various phenomena of the human mind. But though he made some brilliant developements, it is nevertheless true, that he did not advance very far in the general object. He was misled by the pursuit of a few surprising and paradoxical results, and when he had arrived at them he stopped.

After him, and at a short interval, appeared two philosophers, who were more sober-minded, and had better aims. These were Condillac and Hartley. The first work of Condillac appeared some years before the publication of that of Hartley; but the whole of Hartley's train of thought has so much the air of being his own, that there is abundant reason to believe the speculations of both philosophers equally original. They both began upon the ground that all simple ideas are copies of impressions; that all complex ideas are only simple ideas united by the principle of association. They proceeded to examine all the phenomena of the human mind, and were of opinion that the principle of association, or the succession of one simple idea after another, according to certain laws, accounts for the whole; that these laws might, by meditation, be ascertained and applied; and that then the human mind would be understood, as far as man has the means of knowing it.

The merit of Condillac is very great. It may yet, perhaps, be truer to say, that he wrote admirably upon philosophy, than that he was a great philosopher. His power consists in expression; he conveys metaphysical ideas with a union of brevity and clearness which never has been surpassed. But though he professed rather to deliver the opinions of others, than to aim at invention, it cannot be denied that he left the science of the human mind in a much better state than he found it; and this is equivalent to discovery. As a teacher, in giving in this field a right turn to the speculations of his countrymen, his value is beyond all calculation; and perhaps there is no one human being, with the exception of Locke, who was his master, to whom, in this respect, the progress of the human mind is so largely indebted. It is also true, that to form the conception of tracing the sequences among our simple ideas, as the whole of the philosophy of the human mind—(even with the helps which Hume had afforded, and it is more than probable that neither Condillac nor Hartley had ever heard of a work which, according to its author, had fallen dead-born from the press),—was philosophical and sagacious in the highest degree.

It must, however, be allowed, that, in expounding the various mental phenomena of man, Condillac does not display the same penetration and force of mind, nor the same comprehensiveness, as Dr. Hartley. He made great *progress* in showing how those phenomena might be resolved into the sequences of simple ideas; but Dr. Hartley made still greater. We do not mean to pronounce a positive opinion either for or against the grand undertaking of Dr. Hartley, to resolve the whole of the mental phenomena of man into sequences of impressions and of the simple ideas which copy them. But we have no hesitation in saying, that he philosophizes with extraordinary power and sagacity; and it is astonishing how many of the mental phenomena he has clearly resolved; how little, in truth, he has left about which any doubt can remain.

We cannot afford to pursue this subject any farther. This much is ascertained, that the character of the human mind consists in the sequences of its ideas; that the object of education, therefore, is, to provide for the constant production of certain sequences, rather than others; that we cannot be sure of adopting the best means to that end, unless we have the greatest knowledge of the sequences themselves.

In what has been already ascertained on this subject, we have seen that there are two things which have a wonderful power over those sequences. They are, custom, and pain or pleasure. Both of these powers were well remarked by Mr. Hobbes. These are the grand instruments or powers, by the use of which, the purposes of education are to be attained.

Where one idea has followed another a certain number of times, the appearance of the first in the mind is sure to be followed by that of the second, and so on. One of the grand points, then, in the study of education, is, to find the means of making, in the most perfect manner, those repetitions on which the beneficial sequences depend.

When we speak of making one idea follow another, and always that which makes part of a good train, instead of one that makes part of a bad train, there is one difficulty—in this—that each idea, taken singly by itself, is as fit to be a part of a bad train as of a good one; for bad trains and good trains are both made out of the same simple elements. Trains, however, take place by sequences of twos, or threes, or any greater number; and the nature of these sequences, as complex parts of a still greater whole, is that which renders the train either salutary or hurtful. Custom is, therefore, to be directed to two points; first, to form those sequences which make the component parts of a good train; and secondly, to join those sequences together, so as to constitute the train.

When we speak of making one idea follow another, there must always be a starting point; there must be some one idea from which the train begins to flow; and it is pretty evident that much will depend upon this idea. One grand question, then, is—what are the ideas which most frequently operate as the commencement of trains?—that we may by custom attach to them such as are the most beneficent. It has been observed that most, if not all, of our trains, start from a sensation, or some impression upon the external or internal nerves. The question then is, which are those sensations, or aggregates of sensations, which are of the most frequent recurrence? it being obviously of importance, that those which give occasion to the greatest number of trains, should be made, if possible, to give occasion only to the best trains. Now the sensations, or aggregates of sensations, which occur in the ordinary business of life, are those of most frequent recurrence; and from which it is of the greatest importance that beneficial trains should commence. Rising up in the morning, and going to bed at night, are aggregates of this description, common to all mankind; so are the commencement and termination of meals. The practical sagacity of priests, even in the rudest ages of the world, perceived the importance, for giving religious trains an ascendancy in the mind, of uniting them, by early and steady custom, with those perpetually recurring sensations. The morning and evening prayers, the grace before and after meals, have something correspondent to them in the religion of perhaps all nations.

It may appear, even from these few reflections and illustrations, that, if the sensations, which are most apt to give commencement to trains of ideas, are skilfully selected, and the trains which lead most surely to the happiness, first of the individual himself, and next of his fellow-creatures, are by custom effectually united with them, a provision of unspeakable importance is made for the happiness of the race.

Beside custom, it was remarked by Hobbes, that appetite had a great power over the mental trains. But appetite is the feeling toward pleasure or pain in prospect; that is, future pleasure or pain. To say that appetite, therefore, has power over the mental trains, is to say, that the prospect of pleasure or pain has. That this is true, every man knows by his own experience. The best means, then, of applying the prospect of pleasure and pain to render beneficent trains perpetual in the mind, is the thing to be found out, and made familiar to mankind.

The mode in which pleasure and pain affect the trains of the mind is, as ends. That is to say; as a train commences, we have supposed, in some present sensation, so it may be conceived as terminating in the idea of some future pleasure or pain. The intermediate ideas, between the commencement and the end, may be either of the beneficent description or the hurtful. Suppose the sight of a fine equipage to be the commencement; and the riches, which afford it, the appetite, or end, of a train in the mind of two individuals at the same time. The intermediate ideas in the mind of the one are beneficent, in the other hurtful. The mind of the one immediately runs over all the honourable and useful modes of acquiring riches—the acquisition of the most rare and useful qualities—the eager watch of all the best opportunities of bringing them into action—and the steady industry with which they may be applied. That of the other recurs to none but the vicious modes of acquiring riches—by lucky accidents—the arts of the adventurer and impostor—by rapine and plunder, perhaps on the largest scale, by all the honours and glories of war. Suppose the one of these trains to be habitual among individuals, the other not. What a difference for mankind!

It is unnecessary to adduce farther instances for the elucidation of this part of our mental constitution. What, in this portion of the field, requires to be done for the science of education, appears to be, to ascertain, first, what are the ends of human desire, the really ultimate objects at which it points; next, to ascertain what are the most beneficent means of attaining those objects; and lastly, to accustom the mind to fill up the intermediate space between the present sensation and the ultimate object, with nothing but the ideas of those beneficent means. We are perfectly aware that these instructions are far too general. But we hope it will be carried in mind how little, beyond the most general ideas, so confined a sketch as the present can possibly embrace; and we are still not without an expectation that these expositions, general as they are, will not be wholly without their use.

Of the qualities conducive to Happiness.

II. We come now to the second branch of the science of education, or the inquiry what are the qualities with which it is of most importance that the mind of the individual should be endowed. This inquiry we are in hopes the preceding exposition will enable us very materially to abridge. In one sense, it might undoubtedly be affirmed, that all the desirable qualities of the human mind are included in those beneficent sequences of which we have spoken above. But, as it would require, to make this sufficiently intelligible, a more extensive exposition than we are able to afford, we must content ourselves with the ordinary language, and with more familiar mode of considering the subject.

As the object is happiness, that intelligence is one of the qualities in question will not be denied, and may speedily be made to appear. To attain happiness in the greatest possible degree, all the means to that end which the compass of nature affords must be employed in the most perfect possible mode. But all the means which the compass of nature, or the system in which we are placed, affords, can only be known by the most perfect knowledge of that system. The highest measure of knowledge is therefore required. But mere knowledge is not enough; a mere magazine of remembered facts is a useless treasure. Amid the vast variety of known things, there is needed a power of choosing; a power of discerning which of them are conducive, which not, to the ends we have in view. The ingredients of intelligence are two, knowledge and sagacity; the one affording the materials, upon which the other is to be exerted: the one showing what exists, the other converting it to the greatest use; the one bringing within our ken what is capable and what is not capable of being used as means, the other seizing and combining, at the proper moment, whatever is the fittest means to each particular end. This union, then, of copiousness and energy; this possession of numerous ideas, with the masterly command of them, is one of the more immediate ends to which the business of education is to be directed.

With a view to happiness as the end, another quality will easily present itself as indispensable. Conceive that a man knows the materials which can be employed as means, and is prompt and unerring in the mode of combining them; all this power is lost, if there is any thing in his nature which prevents him from using it. If he has any appetite in his nature which leads him to pursue certain things with which the most effectual pursuit of happiness is inconsistent, so far this evil is incurred. A perfect command, then, over a man's appetites and desires; the power of restraining them whenever they lead in a hurtful direction; that possession of himself which insures his judgment against the illusions of the passions, and enables him to pursue constantly what he deliberately approves, is indispensably requisite to enable him to produce the greatest possible quantity of happiness. This is what the ancient philosophers called temperance; not exactly the same with what is called the virtue or grace of temperance, in theological morality, which includes a certain portion (in the doctrines of some theological instructors, a very large portion) of abstinence, and not only of abstinence, or the gratuitous renunciation of pleasure, but of the infliction of voluntary pain. This is done with a view to please the God, or object of worship, and to provide, through his favour, for the happiness of a second or future life. The temperance of the ancient philosophers had a view only to the happiness of the present life; and consisted in the power of resisting the immediate propensity, if yielding to it would lead to an overbalance of evil, or prevent the enjoyment of a superior good, in whatever the good or evil of the present life consists. This resisting power consists of two parts: the power of resisting the allurements of pleasure; and that of resisting the terrors of pain; the last of which has an appropriate name, and is called Fortitude.

These two qualities, the intelligence which can always choose the best possible means, and the strength which overcomes the misguiding propensities, appear to be sufficient for the happiness of the individual himself; to the pursuit of which it cannot be doubted that he has always sufficient motions. But education, we have said, should be an instrument to render the individual the best possible artificer of happiness, not to himself alone, but also to others. What, then, are the qualities with which he ought to be endowed, to make him produce the greatest possible quantity of happiness to others?

It is evident enough to see what is the first grand division. A man can effect the happiness of others either by abstaining from doing them harm, or by doing them positive good. To abstain from doing them harm, receives the name of Justice; to do positive good receives that of Generosity. Justice and generosity, then, are the two qualities by which man is fitted to promote the happiness of his fellow-creatures. And it thus appears, that the four Cardinal Virtues of the ancients do pretty completely include all the qualities, to the possession of which it is desirable that the human mind should be trained. The defect, however, of this description is, that it is far too general. It is evident that the train of mental events which conduct to the proposed results must be far more particularized to insure, in any considerable degree, the effects of instruction; and it must be confessed that the ethical instructions of the ancients failed by remaining too much in generals. What is wanting is, that the incidents of human life should be skilfully classified; both those on the occasion of which they who are the objects of the good acts are pointed out for the receipt of them, and those, on the occasion of which they who are to be the instruments are called upon for the performance. It thus appears that the science of ethics, as well as the science of intellectuals, must be carried to perfection, before the best foundation is obtained for the science of education.

Of the Nature of Happiness.

III. We have spoken of the qualities which are subservient to human happiness, as means to an end. But, before means can be skilfully adapted to an end, the end must be accurately known. To know how the human mind is to be trained to the promotion of happiness, another inquiry, then, is necessary, Wherein does human happiness consist? This is a controverted question; and we have introduced it rather with a view to show the place which it occupies in the theory of education, than that we have it in our power to elucidate a subject about which there is so much diversity of opinion, and which some of the disputants lead into very subtile and intricate inquiries. The importance of the question is sufficiently evident from this, that it is the grand central point, to which all other questions and inquiries converge; that point, by their bearing upon which the value of all other things is determined. That it should remain itself undetermined, implies, that this branch of philosophy is yet far from its highest point of perfection.

The speculations on this subject, too, may be divided into two great classes; that of those who trace up all the elements of happiness, as they do all those of intellect, to the simple sensations which, by their transformation into ideas, and afterwards into various combinations, compose, they think, all the intellectual and moral phenomena of our nature; another, that of those who are not satisfied with this humble origin; who affirm that there is something in human happiness, and in the human intellect, which soars high above this corporeal level; that there are intellectual as well as moral forms, the resplendent objects of human desire, which can by no means be resolved into the grosser elements of sense. These philosophers speak of eternal and immutable truths; truths which are altogether independent of our limited experience; which are truly universal; which the mind recognizes without the aid of the senses; and which are the objects of pure intellect. They affirm, also, that there is a notion of right and of wrong wholly underived from human experience, and independent of the laws which regulate, in this world, the happiness and misery of human life; a right and wrong, the distinction between which is perceived, according to some, by a peculiar sense; according to others, by the faculty which discerns pure truth; according to others by common sense; it is the same, according to some, with the notion of the fitness and unfitness of things; according to others, with the law of nature; according to others, with truth; and there is one eminent philosopher who makes it depend upon sympathy, without determining very clearly whether sympathy depends upon the senses or not.

We cannot too earnestly exhort philosophers to perfect this inquiry; that we may understand at last, not by vague abstract terms, but clearly and precisely, what are the simple ideas included under the term happiness; and what is the real object to which education is pointed; since it is utterly impossible, while there is any vagueness and uncertainty with respect to the end, that there should be the greatest precision and certainty in combining the means.

Of Education in reference to the Means of forming the Mind.

IV. We come at last to the consideration of the means which are at the disposal of man for endowing the human mind with the qualities on which the generation of happiness depends. It is under this head that the discussion of the practical expedients chiefly occurs. It embraces, also, however, some points of theory.

One of the most important of the remaining questions, of that sort, refers to the degree in which the useful qualities of human nature are, or are not, under the powers of education. This is the subject of a famous controversy, with names of the highest authority on both sides of the question. Helvetius, it is true, stands almost alone, on one side. But Helvetius, alone, is a host. No one man, perhaps, has done so much towards perfecting the *theory* of education as Mons. Helvetius; and his books are pregnant with information of the highest importance. Whoever wishes to understand the ground-work of education, can do nothing more conducive to his end, than to study profoundly the expositions of this philosophical inquirer, whether he adopts his conclusions, in all their latitude, or not. That Helvetius was not more admired, in his own country, is owing really to the value of his work. It was too solid, for the frivolous taste of the gay circles of Paris—assemblies of pampered noblesse, who wished for nothing but amusement. That he has been so little valued in this country, is, it must be confessed, owing a little to the same cause; but another has concurred. An opinion has prevailed, a false one, that Helvetius is a peculiarly dangerous enemy to religion: and this has deterred people from reading, or rather the old people, who do not read, have deterred the young who do. There is no book, the author of which does not disguise his unbelief, that can be read with more safety to religion. The author attacks nothing but priestcraft, and that in one of the worst of its forms, the popish priestcraft of the dark and middle ages, the idea of which we are well accustomed, in this country, to separate from that of religion in the abstract. When his phraseology at any time extends, and that is not often, to Christianity itself, or to religion in the abstract, there is nothing calculated to seduce. There is nothing epigrammatic, and sparkling in the expression; nothing sophistical and artfully veiled in the reasoning; a plain proposition is stated, with a plain indication of its evidence; and if your judgment is not convinced, you are not deluded through the fancy.

M. Helvetius says, that if you take men who bring into the world with them the original constituents of their nature, their mental and bodily frame, in that ordinary state of goodness which is common to the great body of mankind,—leaving out of the account the comparatively small number of individuals who come into the world imperfect, and manifestly below the ordinary standard,—you may regard the whole of this great mass of mankind, as equally susceptible of mental excellence; and may trace the causes which make them to differ. If this be so, the power of education embraces every thing between the lowest stage of intellectual and moral rudeness, and the highest state, not only of actual, but of possible perfection. And if the power of education be so immense, the motive for perfecting it is great beyond expression.

The conclusions of Helvetius were controverted directly by Rousseau; and defended, against those strictures, by the author himself. We recollect few writers in this country who have embraced them.* But our writers have contented themselves, rather with rejecting, than disproving; and, at best, have supported their rejection only by some incidental reflection, or the indication of a discrepancy between his conclusions and theirs.

One of the causes, why people have been so much startled, by the extent to which Helvetius has carried the dominion of education, seems to us to arise, from their not including in it nearly so much as he does. They include in it little more than what is expressed by the term schooling; commencing about six or seven years of age, and ending at latest with the arrival of manhood. If this alone is meant by education, it is no doubt true, that education is far indeed from being all-powerful. But if in education is included every thing, which acts upon the being as it comes from the hands of nature, in such a manner as to modify the mind, to render the train of feelings different from what it would otherwise have been; the question is worthy of the most profound consideration. It is probable, that people in general form a very inadequate conception of all the circumstances which act during the first months, perhaps the first moments, of existence, and of the power of those circumstances in giving permanent qualities to the mind. The works of Helvetius would have been invaluable, if they had done nothing more than prove their vast importance, and call to them the concentrated attention of mankind. Rousseau began this important branch of the study of education. He remarked a variety of important facts, which, till his time, had been almost universally neglected, in the minds of infants, and how much might be done, by those who surround them, to give good or bad qualities to their minds, long before the time at which it had been supposed that education could commence. But Helvetius treated the subject much more profoundly and systematically. He traced the circumstances to the very moment of birth; and showed at how wonderfully early an age indelible characters might be impressed; nay, that of the circumstances over which man has a control (for he speaks not of others), some may be traced even beyond the birth, on which effects of the greatest importance depend.

It is evident how much it imports the science of education, that these circumstances should, by careful and continued observation, be all ascertained, and placed in the order best adapted for drawing from them the most efficient practical rules. This is of more importance than determining the question, whether the prodigious difference which exists among men, ordinarily well organized, is owing wholly to the circumstances which have operated upon them since the first moment of their sensitive existence, or is in part produced by original peculiarities. Enough is ascertained to prove, beyond a doubt, that if education does not perform every thing, there is hardly any thing which it does not perform: that nothing can be more fatal than the error of those who relax in the vigilance of education, because nature is powerful, and either renders it impossible for them to accomplish much, or accomplishes a great deal without them: that the feeling is much more conformable to experience, and much more conformable to utility, which ascribes every thing to education, and thus carries the motive for vigilance and industry, in that great concern, to its highest possible pitch. This much, at any rate, is ascertained, that all the difference which exists, or can ever be made to exist, between one body, or class of men, and another, is wholly owing to education. Those peculiarities, if any such there be, which sink a man below, or elevate him above the ordinary state of aptitude to profit by education, have no operation in the case of large numbers or bodies. But large numbers or bodies of men are raised to a high degree of mental excellence; and might, without doubt, be raised to still higher. Other large bodies, or whole nations, have been found in so very low a mental state, as to be raised but little above the brutes. All this vast distance is undeniably the effect of education. This much, therefore, may be affirmed on the side of Helvetius, that a prodigious difference is produced by education; while, on the other hand, it is rather assumed than proved, that any difference exists, but that which difference of education creates.

Of the Physical circumstances which operate in forming the Mind.

The circumstances which are included under the term Education, in the comprehensive sense in which we have defined it, may be divided, we have said, into Physical and Moral. We shall now consider the two classes in the order in which we have named them; and have here again to remind the reader, that we are limited to the task of pointing out what we should wish to be done, rather than permitted to attempt the performance.

1. Three things are desirable with regard to the physical circumstances, which operate in the way of education favourably or unfavourably; to collect them fully; to appreciate them duly; and to place them in the order which is most favourable for drawing from them practical rules.

This is a service (common to the sciences of education and mind) which has been very imperfectly rendered. It has been chiefly reserved to medical men to observe the physical circumstances which affect the body and mind of man; but of medical men few have been much skilled in the observation of mental phenomena, or have thought themselves called upon to mark the share which physical circumstances had in producing them. There are indeed some, and those remarkable exceptions. There is Dr. Darwin in our own country, and M. Cabanis in France. They have both of them taken the mind as a part at least of their study; and we are highly indebted to them for the number and value of their observations. They are both philosophers, in the most important sense of the word; they both observed nature for themselves, observed her attentively, and with their view steadily directed to the proper end. But still it was not safe to rely upon them implicitly as guides. They were in too great a haste to establish conclusions; and were apt to let their belief run before their evidence. They were not sufficiently careful to distinguish between the different degrees of evidence, and to mark what is required to constitute proof. To do this steadily seems, indeed, to be one of the rarest of all endowments; and was much less the characteristic of the two philosophers we have named, than a wide range of knowledge from which they collected the facts, and great ingenuity in combining and applying them. Dr. Darwin was the most remarkable, both for the strength and the weakness of which we speak. The work of Darwin, to which we chiefly allude, is the *Zoonomia;* though important remarks to the same effect are scattered in his other publications. Cabanis entitled his great work, *Rapports du Physique et du Moral de l'Homme*. And there are some works recently announced by German physiologists, the titles of which promise aids in the same endeavour. But though we expect from them new facts, and ingenious hints, we have less hope of any great number of sound conclusions.

---

* There is one brilliant authority on the side of Helvetius: "It was a favourite opinion of Sir William Jones, that all men are born with an equal capacity of improvement." Lord Teignmouth's *Life of Sir William Jones*, Vol. II. p. 211.

There are certain general names, already in use, including the greater number of the physical circumstances which operate in the way of education upon the mind. It will be convenient, because of their commonness, to make use of them on the present occasion, though neither the enumeration which they make is complete, nor the distribution logical.

All the physical circumstances which operate upon the mind are either, 1. inherent in the body: or, 2. external to the body Those which are external to the body operate upon the mind, by first operating upon the body.

Of the first kind, the more remarkable seem to be healthiness or sickliness, strength or weakness, beauty or deformity, the temperament, the age, the sex.

Of the second sort, the more remarkable seem to be the aliment, the labour, the air, temperature, action, rest.

Previous to the inquiry respecting the power which physical circumstances exert in the formation of the mind, it may seem that we ought to determine the speculative question respecting the nature of the mind: that is, whether the phenomena of mind may possibly result from a certain organization of the powers of matter; or whether something of a different kind, and which we call spiritual, must not be conceived, as the source and organ of thought. We do not mean to enter into this controversy, which would detain us too long. It is not, in the least degree, necessary that we should, for the end which we have in view. Whether the one hypothesis, with respect to the mind, be adopted, or the other, the distribution of the circumstances, which operate in the formation of human character, into those commonly called Physical, and those commonly called Moral, will be as convenient a distribution, as the present state of our knowledge enables us to make. And all that inquiry can do, in regard to those circumstances, is, to trace them accurately, and to observe their effects; that is, to ascertain what they are, and what the order of the mental events by which they are followed. This is simply matter of experience; and what we experience is what it is, whatever opinion we adopt with regard to the nature of that which thinks. It is in what we experience, all ascertained, and put into the best possible shape for ease of comprehension and ready application to practice, that all useful knowledge on this, as on all other subjects, consists.

1. First we are to consider the circumstances of the body which have an effect upon the mental sequences. The object is, to ascertain which have a tendency to introduce those sequences which are favourable, which to introduce those that are unfavourable, to human happiness, and how to turn this knowledge to account.

Health and sickness, or the states of body which those names most peculiarly express, are the first of the circumstances which we have enumerated under this head. That these states have a tendency to introduce very different trains of thought is matter of vulgar experience; but very little has been done to examine such trains, and to ascertain what in each is favourable, and what is unfavourable to human happiness.

We have already seen, that the trains which are favourable to Intelligence, Temperance, Generosity, and Justice, are the trains favourable to human happiness. Now, with respect to Intelligence, it will be seen, that Health is partly favourable, and partly unfavourable; and the same is the case with sickness. Health is favourable, by allowing that time to be given to study, which many kinds of sickness withdraws; by admitting a more vigorous attention, which the pain and languor of sickness often divide. It is unfavourable, by introducing that flow of pleasurable ideas, which is called high spirits, in a degree unfavourable to the application of attention; and by leading to that passionate pursuit of pleasure, which diminishes, if it does not destroy, the time for study. The mode in which disease operates upon the mental sequences is a subject of great complexity, and in which little has yet been done to mark distinctly the events, and ascertain the order of their succession. Cabanis, in his seventh memoir, entitled, *De l'Influence des Maladies sur la Formation des Idées et des Affections Morales*, has made a useful beginning toward the elucidation of this subject; but here, as elsewhere, he is too often general and vague. Instruction may also be gleaned from Darwin; but the facts which bear upon this point rather drop from him incidentally, than are anywhere put together systematically for its elucidation. As they were both physicians, however, of great experience, and of unusual skill in the observation of mental phenomena, their opinions are entitled to the greatest respect. The result of the matter is, that an improved medicine is no trifling branch of the art and science of education. Cabanis, accordingly, concludes his memoir with the two following propositions:

" *1mo*, L'état de maladie influe d'une manière directe sur la formation des idées et des affections morales: nous avons même pu nontrer dans quelques observations particulières, comment cette influence s'exerce.

" *2do*, L'observation et l'experience nous ayant fait decouvrir les moyens de combattre assez souvent avec succés l'etat de maladie, l'art qui met en usage ces moyens, peut donc modifier et perfectionner les operations de l'intelligence et les habitudes de la volonté."

As it is chiefly through the nervous system, and the centre of that system, the brain, that the mental sequences are affected, and as all the sensitive parts have not an action equally strong, nor equally direct, upon the nerves and brain, diseases affect the mental sequences differently, according to the parts which they invade. The system of the nerves and brain is itself subject to different states of disease. Classified, with regard to the functions which that system performs, as the organ of sensibility and of action, these states are thus described by M. Cabanis: " 1. Excess of sensibility to all impressions on the one part; excessive action on the organs of motion on the other. 2. Unfitness to receive impressions, in sufficient number, or with the due degree of energy; and a diminution of the activity necessary for the production of the motions. 3. A general disturbance of the functions of the system, without any remarkable appearance of either excess or defect. 4. A bad distribution of the cerebral virtue, either when it exerts itself unequally in regard to time, having fits of extraordinary activity, followed by others of considerable remission; or when it is supplied in wrong proportion to the different organs, of which some are to a great degree abandoned, while there appears in others a concentration of sensibility, and of the excitations or powers by which the movements are affected."

The effects upon the mental sequences are represented in the following general sketch, which has the advantage of being tolerably comprehensive, though it is unhappily both vague and confused: " We may lay it down as a general fact, that, in all the marked affections of the nerves, irregularities, less or greater, take place, relative both to the mode in which impressions are received, and to the mode in which the determinations, automatic or voluntary, are formed. On one part, the sensations vary incessantly and rapidly with respect to their vivacity, their energy, and even their number; on another, the strength, the readiness, the facility of action exhibit the greatest inequalities. Hence perpetual fluctuation, from great excitement to languor, from elevation to dejection; a temper and passions variable in the highest degree. In this condition, the mind is always easily pushed to extremes. Either the man has many ideas, with great mental activity and acuteness; or he is, on the contrary, almost incapable of thinking. It has been well observed, that hypochondriacal persons are by turns both courageous and cowardly; and as the impressions are habitually faulty either by excess or defect, in regard to almost all objects, it is seldom that the images correspond to the reality of things; that the desires and the will obtain the proper force and direction. If, at the same time with these irregularities, which arise from the nervous system, should be found a weakness of the muscular organs, or of some important viscus, as, for example, of the stomach,—the phenomena, though still analagous in the main, will be distinguished by remarkable peculiarities. During the interval of languor, the debility of the muscles will render the sense of weakness, the fainting and drooping, still more complete and oppressive; life will appear ready to escape at every instant. The passions are gloomy, excited by trifles, selfish; the ideas are petty, narrow, and bear only upon the objects of the slightest sensations. At the times of excitation, which arrive the more suddenly, the greater the weakness; the muscular determinations do not obey the impulses of the brain, unless by starts, which have neither energy nor duration. These impulses serve only to convince the patient more profoundly of his real imbecility; they give him only a feeling of impatience, of discontent, and anxiety. Desires, often sufficiently keen, but commonly repressed by the habitual feeling of weakness, still more increase the discouraging impression. As the peculiar organ of thought cannot act without the concurrence of several others, and as, at that moment, it partakes in some degree of the weakness which affects the organs of movement, the ideas present themselves in crowds; they spring up, but do not arrange themselves in order; the necessary attention is not enjoyed; the consequence is, that this activity of the imagination, which we might expect to afford some compensation for the absence of other faculties, becomes a new source of dejection and despair."

In this passage, the mental sequences which particular states of disease introduce are clearly shown to have a prodigious influence upon human happiness; but the effects which are produced in respect to intelligence, temperance, generosity, and justice, are mixed up together; and the author rather shows how much this subject deserves to be studied, than gives us information from which any considerable degree of practical utility can be derived. The connection between particular states of body, and particular mental trains, must be carefully watched and recorded. When the events, one by one, are accurately distinguished, and made easy to be recognised, and when the order in which they follow one another is known, our power over the trains of those events; power to prevent such as are unfavourable, to produce such as are favourable, to human happiness, will then be at its height: and how to take care of his health will be one of the leading parts of the moral and intellectual education of

The state of the body, with regard to health and disease, is the inherent circumstance of the greatest importance, and we must pass over the rest with a cursory notice. The next we mentioned, are, strength and weakness, meaning chiefly muscular strength and weakness; and the natural, habitual, not the accidental, or diseased, state. It is a common enough observation, that muscular strength is apt to withdraw the owner from mental pursuits, and engage him in such as are more of the animal kind; the acquisition and display of physical powers. Few men of great bodily powers have been much distinguished for mental excellence; some of the greatest ornaments of human nature have been remarkable for bodily weakness. Muscular strength is liable to operate unfavourably upon the moral, as well as the intellectual trains of thought. It diminishes that respect for other men, which is so necessary to resist the impulses of passion; it presents innumerable occasions for playing the tyrant with impunity; and fosters, therefore, all that train of ideas, in which the tyrannical vices are engendered. Cabanis remarks, and the fact is worthy of the greatest attention:—"Presque tous les grands scélérats sont des hommes d'une structure organique vigoureuse, remarquables par la fermeté et la tenacité de leurs fibres musculaires." It is evident, therefore, how deeply it concerns the happiness of mankind, that the mental trains which this circumstance has a tendency to raise, should be accurately known, as thus alone the means can be known, how that which is hurtful can be avoided, that which is useful be introduced.

Of beauty and deformity, as inherent circumstances which have an effect upon the mental trains, much will not be necessary to be said. Illustrations will occur to every body, to prove, that their power is not inconsiderable; so little, however, has been done to ascertain the facts, and record them in the best possible order, that any thing which deserves the name of knowledge on the subject hardly exists; and the principal service we can render is to point it out for study; to exhort future inquirers, to observe diligently the trains which flow from beauty and deformity as their source, and to trace to the largest possible sequences, as above described, the connections which take place between them. Beauty and deformity it may be observed, operate upon the mental trains in somewhat a different way from health and disease; rather mediately than immediately. It is the idea of their effect upon other people that is the more immediate cause of the trains to which they give occasion. The idea that beauty commands their favourable regards, is apt to introduce the well-known trains, denoted by the terms, vanity, pride, contemptuousness, trains not very favourable to the virtues. The idea that deformity is apt to excite their unfavourable regards, is often observed to lead to acuteness and vigour of intellect, employed as instruments of protection, but to moroseness, and even malignity of temper. The mode, however, in which beauty and deformity operate upon the mental trains, namely, through the idea of their effect upon other people, is common to them with a great many other advantages or disadvantages, which derive their value chiefly from their influence upon other people; and materials for the illustration of this subject have been supplied by various writers upon the human mind.

To the word Temperament, no very precise idea has hitherto been annexed. It may be conceived in the following manner: The bodily structure, the composition of elements in the body of every individual, is different from that in the body of any other. It is observed, however, that the composition is more nearly resembling in some, than in others; that those who thus resemble may be arranged in groups; and that they may all be comprehended in four or five great classes. The circumstances, in which their bodily composition agrees, so as to constitute one of those large classes, have been called the Temperament; and each of those more remarkable characters of the body has been observed to be attended with a peculiar character in the train of ideas. But the illustration of the trains of ideas, and hence of the qualities of mind, which are apt to be introduced by temperament, and by the diversities of age and of sex, we are obliged, by the rapid absorption of the space allotted us, wholly to omit. The subject in itself is not very mysterious. Accurate observation, and masterly recordation alone are required. To be sure, the same may be said of every object of human inquiry. But in some cases, it is not so easy to conceive perfectly what observation and recordation mean. On these topics, also, we are happy to say, that Cabanis really affords very considerable helps.

We come now to the second sort of physical circumstances, which have the power of introducing habitually certain trains of ideas, and hence of impressing permanent tendencies on the mind,—the circumstances which are external to the body. Some of these are of very great importance. The first is Aliment.

Aliment is good or evil, by quality, and quantity. Hartley has remarked long ago, that though all the impressions from which ideas are copied, are made on the extremities of the nerves which are ramified on the surface of the body, and supply the several organs of sense, that other impressions are nevertheless made on the extremities of the nerves which are ramified on the internal parts of our bodies, and that many of those impressions are associated with trains of ideas; that the impressions made upon the extremities of the nerves which are ramified on the alimentary canal, are associated with the greatest number of those trains; and of such trains, that some are favourable to happiness, some altogether the reverse. If the quantity and quality of the aliment be the principal cause of those impressions, attended by such important effects, here is a physiological reason, of the greatest cogency, for an accurate observation and recordation of the events occurring in this part of the field; of what antecedents are attended by what consequents, and what are the largest sequences which can be traced. Cabanis confirmed this doctrine with regard to the internal impressions, and added another class. He said that not only the extremities of the nerves which terminate internally, but the centre of the nervous influence, the brain itself, received impressions, and that thus there were no fewer than three sources of the mental and corporeal movements of man; one external, from which almost all our distinct ideas are copied; and two internal, which exert a very great influence upon the train of ideas, and hence upon the actions of which these trains are the antecedents or cause.

On this, too, as on most of the other topics, belonging to the physical branch of education, we must note, as still uncollected, the knowledge which the subject requires. It is understood in a general way, that deep impressions are by this means made upon the mind; but how they are made, is a knowledge which, in any such detail and accuracy as to afford useful practical rules, is nearly wanting. There is a passage in Hartley, which we esteem it important to quote: "The sense of feeling may be distinguished into that of the external surface of the body, and that of the cavities of the nose, mouth, fauces, alimentary duct, pelvis, of the kidneys, ureters, bladder of urine, gall-bladder, follicles, and ducts of the glands, &c. The sensibility is much greater in the last than in the first, because the impressions can more easily penetrate through the soft epithelium with which the internal cavities are invested. In the mouth and nose this sensibility is so great, and attended with such distinguishing circumstances, as to have the names of taste and smell assigned respectively to the sensations impressed upon the papillæ of these two organs." . . . . "The taste may also be distinguished into two kinds; viz. the general one which extends itself to the insides of the lips and cheeks, to the palate, fauces, œsophagus, stomach, and whole alimentary duct, quite down to the anus. . . . . . The pleasures of the taste, considered as extending itself from the mouth through the whole alimentary duct, are very considerable, and frequently repeated; they must, therefore, be one chief means, by which pleasurable states are introduced into the brain and nervous system. These pleasurable states must, after some time, leave miniatures of themselves, sufficiently strong to be called up upon slight occasions, viz. from a variety of associations with the common visible and audible objects, and to illuminate these and their ideas. When groups of these miniatures have been long and closely connected with particular objects, they coalesce into one complex idea, appearing, however, to be a simple one; and so begin to be transferred upon other objects, and even upon tastes back again, and so on without limits. And from this way of reasoning it may now appear, that a great part of our intellectual pleasures are ultimately deducible from those of taste; and that one principal final cause of the greatness and constant recurrency of these pleasures, from our first infancy to the extremity of old age, is to introduce and keep up pleasurable states in the brain, and to connect them with foreign objects. The social pleasures seem, in a particular manner, to be derived from this source, since it has been customary in all ages and nations, and is in a manner necessary, that we should enjoy the pleasures of taste in conjunction with our relations, friends, and neighbours. In like manner, nauseous tastes, and painful impressions upon the alimentary duct, give rise and strength to mental pains. The most common of these painful impressions is that from excess, and the consequent indigestion. This excites and supports those uneasy states, which attend upon melancholy, fear, and sorrow. It appears also to me, that these states are introduced in a great degree during sleep, during the frightful dreams, agitations, and oppressions, that excess in diet occasions in the night. These dreams and disorders are often forgotten; but the uneasy states of body which then happen, leave vestiges of themselves, which increase in number and strength every day from the continuance of the cause, till at last they are ready to be called up in crowds upon slight occasions, and the unhappy person is unexpectedly, and at once, as it were, seized with a great degree of the hypochondriac distemper, the obvious cause appearing no ways proportionable to the effect. And thus it may appear that there ought to be a great reciprocal influence between the mind and alimentary duct, agreeably to common observation." Cabanis, in like manner, says, "Quoique les médecins aient dit plusieurs choses hazardées, touchant l'effet des substances alimentaires sur les organs de la pensée, ou sur les principes physiques de nos penchans, il n'en est pas moins certain que les differentes causes que nous appliquons journellement à nos corps, pour en renouveller les mouvemens, agissent avec une grande efficacité sur nos dispositions morales. On se rend plus propre aux travaux de l'esprit par certaines precautions de régime, par l'usage, ou la suppression, de certains alimens. Quelques personnes ont été guéries de violens accès de colere, auxquels elles etoient sujètes, par la seule diète pythagorique, et dans le cas même ou des délires furieux troublent toutes les facultés de l'ame, l'emploi journalier de certaines nourritures ou de certaines boissons, l'impression d'une certaine temperature de l'air, l'aspect de certaines objets; en un mot, un systême diététique particulier suffit souvent pour y remener le calme, pour faire tout rentrer dans l'ordre primitif."

As it is impossible for us here to attempt a full account of the mode in which aliments operate to produce good or bad effects upon the train of ideas, we shall single out that case, which, as operating upon the greatest number of people, is of the greatest importance; we mean that, in which effects are produced by the *poverty* of the diet; proposing, under the term poverty, to include both badness of quality, and defect of quantity. On badness of quality, we shall not spend many words. Aliments are bad in a variety of ways, and to such a degree as to impair the health of body. Of such, the injurious effect will not be disputed. Others, which have in them no hurtful ingredient, may contain so insignificant a portion of nourishment, that to afford it in the requisite degree, they must produce a hurtful distention of the organs. The saw-dust, which some northern nations use for bread, if depended upon for the whole of their nourishment, would doubtless have this effect. The potatoe, where solely depended upon, is not, perhaps, altogether free from it. Bad quality, however, is but seldom resorted to, except in consequence of deficient quantity. That is, therefore, the principal point of inquiry.

It is easy to see a great number of ways in which deficient quantity of food operates unfavourably upon the *moral* temper of the mind. As people are ready to sacrifice every thing to the obtaining of a sufficient quantity of food, the want of it implies the most dreadful poverty—that state, in which there is scarcely any source of pleasure, and in which almost every moment is subject to pain. It is found by a very general experience, that a human being, almost constantly in pain, hardly visited by a single pleasure, and almost shut out from hope, loses by degrees all sympathy with his fellow creatures; contracts even a jealousy of their pleasures, and at last a hatred; and would like to see all the rest of mankind as wretched as himself. If he is habitually wretched, and rarely permitted to taste a pleasure, he snatches it, with an avidity; and indulges, with an intemperance, almost unknown to any other man. The evil of insufficient food acts with an influence not less malignant upon the intellectual, than upon the moral, part of the human mind. The physiologists account for its influence in this manner. They say, that the signs, by which the living energy is manifested, may be included generally under the term *irritability,* or the power of being put in action by stimulants. It is not necessary for us to be very particular in explaining these terms; a general conception will for the present suffice. There is a certain degree of this irritability in the frame of man, upon which the proper state, or rather the very existence, of the animal functions seems necessarily to depend. A succession of stimulants, of a certain degree of frequency and strength, is necessary to preserve that irritability. The most important by far of all the useful stimulants applied to the living organs is food. If this stimulant is applied, in less than a sufficient degree, the irritability is diminished in proportion, and all those manifestations of the living energy which depend upon it, mental as well as corporeal, are impaired; the mind loses a corresponding part of its force. We must refer to the philosophical writers on medicine for illustrations and facts, which we have not room to adduce, but which will not be difficult to collect. Dr. Crichton places *poor diet* at the head of a list of causes which "weaken attention, and consequently debilitate the whole faculties of the mind."* From this fact, about which there is no dispute, the most important consequences arise. It follows, that when we deliberate about the means of introducing intellectual and moral excellence into the minds of the principal portion of the people, one of the first things which we are bound to provide for, is, a generous and animating diet; the physical causes must go along with the moral; and nature herself denies, that you shall make a wise and virtuous people, out of a starving one. Men must be happy themselves, before they can rejoice in the happiness of others; they must have a certain vigour of mind, before they can, in the midst of habitual suffering, resist a presented pleasure; their own lives, and the causes of their well-being, must be worth something, before they can value, as to respect, the life, or well-being, of any other person. This or that individual may be an extraordinary individual, and exhibit mental excellence in the midst of wretchedness; but a wretched and excellent people never yet has been seen on the face of the earth. Though far from fond of paradoxical expressions, we are tempted to say, that a good diet is a necessary part of a good education; for in one very important sense it is emphatically true. In the great body of the people all education is impotent without it.

Labour is the next of the circumstances in our enumeration. We have distinguished labour from action, though action is the genus of which labour is one of the species; because of those species, labour is so much the most important. The muscular operations of the body, by which men generally earn their bread, are the chief part of the particulars which we include under that term. The same distinction is useful here as in the former case; labour is apt to be injurious by its *quality,* and by its *quantity.* That the quality of the labour, in which a man is employed, produces effects, favourable or unfavourable upon his mind, has long been confessed. Dr. Smith made the important remark, that the labour in which the great body of the people are employed, has a tendency to grow less and less favourable, as civilization and the arts proceed. The division and subdivision of labour is the principal cause. This confines the attention of the labourer to so small a number of objects, and so narrow a circle of ideas, that the mind receives not that varied exercise, and that portion of aliment, on which almost every degree of mental excellence depends. When the greater part of a man's life is employed in the performance of a few simple operations, in one fixed invariable course, all exercise of ingenuity, all adaptation of means to ends, is wholly excluded and lost, as far as disuse can destroy the faculties of the mind. The minds, therefore, of the great body of the people are in danger of really degenerating, while the other elements of civilization are advancing, unless care is taken, by means of the other instruments of education, to counteract those effects which the simplification of the manual processes has a tendency to produce.

The *quantity* of labour is another circumstance which deserves attention, in estimating the agents which concur in forming the mind. Labour may be to such a degree severe, as to confine the attention almost wholly to the painful ideas which it brings; and to operate upon the mind with nearly the same effects as an habitual deficiency of food. It operates perhaps still more rapidly; obliterating sympathy, inspiring cruelty and intemperance, rendering impossible the reception of ideas, and paralyzing the organs of the mind. The attentive examination, therefore, of the facts of this case, as a matter of first rate importance. Two things are absolutely certain:—that without the bodily labour of the great bulk of mankind, the well-being of the species cannot be obtained;—and that, with the bodily labour of the great bulk of mankind, carried beyond a certain extent, neither intellect, virtue, nor happiness can flourish upon the earth. What, then, is that precious middle point, at which the greatest quantity of good is obtained with the smallest quantity of evil, is, in this part of the subject, the problem to be solved.

---

* *An Inquiry into the Nature and Origin of Mental Derangement, &c.* By A. Crichton, M. D. I. 274.

The state of defective food and excessive labour, is the state in which we find the great bulk of mankind; the state in which they are either constantly existing, or into which they are every moment threatening to fall. These are two, therefore, in settling the rank among the circumstances which concur in determining the degree of intellect and morality capable of being exhibited in the societies of men, which ought to stand in a very eminent place: the mode of increasing to the utmost, the quantity of intellect, morality, and happiness, in human society, will be very imperfectly understood, 'till they obtain a new degree of consideration.

We named, still farther, among the physical circumstances which contribute to give permanent characters to the mind, air, temperature, action, and rest. But of these we must leave the illustration wholly to other inquirers. It is mortifying to be obliged to leave a subject, on which so much depends, and for which so little has been done, with so very imperfect an attempt for its improvement. We shall, however, have performed a service of some utility to education, if what we have said has any tendency to lead men to a juster estimate of the physical circumstances which concur in fashioning the human mind, and hence to greater industry and care in studying and applying them.

Of the *Moral* circumstances which operate in forming the Mind.

2. The moral circumstances which determine the mental trains of the human being, and hence the character of his actions, are of so much importance, that to them the term education has been generally confined: Or rather, the term education has been generally used in so narrow a sense, that it embraces only one of the four classes into which we have thought it convenient to distribute the moral circumstances which operate to the formation of the human mind.

The first of these classes we have comprehended under the term *Domestic Education.* To this the groundwork of the character of most individuals is almost wholly to be traced. The original features are fabricated here; not, indeed, in such a manner as to be unsusceptible of alteration, but in such a manner, decidedly, as to present a good or bad subject for all future means of cultivation. The importance, therefore, of domestic education, needs no additional words to explain it; though it is difficult to restrain a sigh, when we reflect, that it has but now begun to be regarded as within the pale of education; and a few scattered remarks, rather than a full exposition of the subject, is all the information upon it, with which the world has been favoured.

By Domestic Education, we denote all that the child hears sees, more especially all that it is made to enjoy at the hands of others, and all that it is allowed or constrained to do, in the house in which it is born and bred, which we shall consider generally as the parental.

If we consider that the mental trains, as explained above, are that upon which every thing depends, and that the mental trains depend essentially upon those sequences among our sensations which have been so frequently experienced as to create a habit of passing from the idea of the one to that of the other,—we shall perceive immediately the reasons of what we have advanced.

It seems to be a law of human nature, that the first sensations experienced produce the greatest effects; more especially, that the earliest repetitions of one sensation after another produce the deepest habit; the strongest propensity to pass immediately from the idea of the one to the idea of the other. Common language confirms this law, when it speaks of the susceptibility of the tender mind. On this depends the power of those associations which form some of the most interesting phenomena of human life. From what other cause does it arise, that the hearing of a musical air, which, after a life of absence, recalls the parental mansion, produces as it were a revolution in the whole being? That the sympathies between brothers and sisters are what they are? On what other cause originally is the love of country founded?—that passionate attachment to the soil, the people, the manners, the woods, the rivers, the hills, with which our infant eyes were familiar, which fed our youthful imaginations, and with the presence of which the pleasures of our early years were habitually conjoined!

It is, then, a fact, that the early sequences to which we are accustomed form the primary habits; and that the primary habits are the fundamental character of the man. The consequence is most important; for it follows, that, as soon as the infant, or rather the embryo, begins to feel, the character begins to be formed; and that the habits which are then contracted, are the most pervading and operative of all. Education, then, or the care of forming the habits, ought to commence, as much as possible, with the period of sensation itself; and, at no period, is its utmost vigilance of greater importance, than the first.

Very unconnected, or very general instructions, are all that can be given upon this subject, till the proper decompositions and recompositions are performed; in other terms, till the subject is first analyzed, and then systematized; or, in one word, *philosophized*, if we may use that verb in a passive signification. We can, therefore, do little more than exhort to the prosecution of the inquiry.

The steady conception of the End must guide us to the Means. Happiness is the end; and we have circumscribed the inquiry, by naming Intelligence, Temperance, and Benevolence, of which last the two parts are Generosity and Justice, as the grand qualities of mind through which this end is to be attained. The question, then, is, how can those early sequences be made to take place on which the habits, conducive to intelligence, temperance, and benevolence, are founded; and how can these sequences, on which are founded the vices opposite to those virtues, be prevented?

Clearness is attained, by disentangling complexity: we ought, therefore, to trace the sequences conducive to each of those qualities in their turn. A part, however, must suffice, when we cannot accomplish the whole. Intelligent trains of ideas constitute intelligence. Now trains of ideas are intelligent, when the sequences in the ideas correspond to the sequences in nature. A man, for example, knows the order of certain words, when his idea of the one follows that of the other, in the same order in which the events themselves took place. A man is sagacious in devising means for the production of events when his ideas run easily in trains which are at once agreeable to knowledge, that is, to the trains of events, and, at the same time, new in the combination. They must be agreeable to knowledge; that is, one of the ideas must follow another in the order in which the objects of which they are the ideas follow one another in nature, otherwise the train would consist of mere chimeras, and, having no connection with things, would be utterly useless. As the event, however, is not in the ordinary course, otherwise sagacity would not be required to give it existence, the ordinary train of antecedents will not suffice; it must be a peculiar train, at once correspondent with nature, and adapted to the end. The earliest trains, produced in the minds of children, should be made to partake as much as possible of those characters. The impressions made upon them should correspond to the great and commanding sequences established among the events on which human happiness principally depends. More explicitly, children ought to be made to see, and hear, and feel, and taste, in the order of the most invariable and comprehensive sequences; in order that the ideas which correspond to their impressions, and follow the same order of succession, may be an exact transcript of nature, and always lead to just anticipations of events. Especially, the pains and pleasures of the infant, the deepest impressions which he receives, ought, from the first moment of sensation, to be made as much as possible to correspond to the real order of nature. The moral procedure of parents is directly the reverse; who strive to defeat the order of nature, in accumulating pleasures to their children, and in preventing the arrival of pains, when the children's own conduct would have had very different effects.

Not only are the impressions, from which ideas are copied, made, by the injudicious conduct of those to whom the destiny of infants is confided, to follow an order very different from the natural one, or that in which the grand sequences among events would naturally produce them; but wrong trains of ideas, trains which have no correspondence to the order of events, are often introduced immediately by words, or other signs of the ideas, of other men. As we can only give very partial examples of a general error, we may content ourselves with one of the most common. When those who are about children express by their words, or indicate by other signs, that terrific trains of ideas are passing in their minds, when they go into the dark; terrific trains, which have nothing to do with the order of events, come up also in the minds of the children in the dark, and often exercise an uncontrollable sway during the whole of their lives.—This is the grand source of wrong education; to this may be traced the greater proportion of all the wrong biases of the human mind.—If an order of ideas, correspondent to the order of events, were taught to come up in the minds of children when they go into the dark, they would think of nothing but the real dangers which are apt to attend it, and the precautions which are proper to be taken; they would have no wrong feelings, and their conduct would be nothing but that which prudence, or a right conception of the events, would prescribe.—If the expressions, and other signs of the ideas, of those who are about children, indicate that trains, accompanied with desire and admiration, pass in their minds when the rich and powerful are named, trains accompanied with aversion and contempt when the weak and the poor; the foundation is laid of a character stained with servility to those above, and tyranny to those below.—If indication is given to children that ideas of disgust, of hatred, and detestation, are passing in the minds of those about them, when particular descriptions of men are thought of; as men of different religions, different countries, or different political parties in the same country, a similar train becomes habitual in the minds of the children, and those antipathies are generated which infuse so much of its bitterness into the cup of human life.

We can afford to say but very few words on the powers of domestic education with regard to Temperance. That virtue bears a reference to pain and pleasure. The grand object evidently is, to connect with each pain and pleasure those trains of ideas, which, according to the order established among events, tends most effectually to increase the sum of pleasures upon the whole, and diminish that of pains. If the early trains create a habit of over-valuing any pleasure or pain, too much will be sacrificed during life to obtain the one, or avoid the other, and the sum of happiness, upon the whole, will be impaired. The order in which children receive their impressions, as well as the order of the trains which they copy from others, has a tendency to create impatience under privation; in other words, to make them in prodigious haste to realize a pleasure as soon as desired, to extinguish a pain as soon as felt. A pleasure, however, can be realized in the best possible manner, or a pain removed, only by certain steps,—frequently numerous ones; and if impatience hurries a man to overlook those steps, he may sacrifice more than he gains. The desirable thing would be, that his ideas should always run over those very steps, and none but them; and the skilful use of the powers we have over the impressions and trains of his infancy would lay the strongest foundation for the future happiness of himself, and of all those over whom his actions have any sway. It is by the use of this power that almost every thing is done to create what is called the temper of the individual; to render him irascible on the one hand, or forbearing on the other; severe and unforgiving, or indulgent and placable.

Intelligence and Temperance are sometimes spoken of, as virtues which have a reference to the happiness of the individual himself: Benevolence as a virtue which has a reference to the happiness of others. The truth is, that intelligence and temperance have a reference not less direct to the happiness of others than to that of the individual; and Benevolence cannot be considered as less essential than they to the happiness of the individual. In reality, as the happiness of the individual is bound up with that of his species, that which affects the happiness of the one, must also, in general, affect that of the other.

It is not difficult, from the expositions we have already given, to conceive in a general way, how sequences may take place in the mind of the infant, which are favourable to benevolence, and how sequences may take place which are unfavourable to it. The difficulty is, so to bring forward and exhibit the details, as to afford the best possible instruction for practice. We have several books now in our own language, in particular those of Miss Edgeworth, which afford many finely selected instances, and many detached observations of the greatest value, for the cultivation of benevolence in the infant mind. But the great task of the philosopher, that of *theorizing* the whole, is yet to be performed. What we mean by "theorizing the whole," after the explanations we have already afforded, is not, we should hope, obscure. It is, to observe exactly the facts; to make a perfect collection of them, nothing omitted that is of any importance, nothing included of none; and to record them in that order and form, in which all that is best to be done in practice (that is, in what manner the sequences established in nature may be turned most effectually to the production of a certain end) can be most immediately and certainly perceived.

The order of the impressions which are made upon the child by the spontaneous order of events, is, to a certain degree, favourable to benevolence. The pleasures of those who are about him are most commonly the cause of pleasure to himself; their pains of pain. When highly pleased, they are commonly more disposed to exert themselves to gratify him. A period of pain or grief in those about him, is a period of gloom,—a period in which little is done for pleasure,—a period in which the pleasures of the child are apt to be overlooked. Trains of pleasurable ideas are thus apt to arise in his mind, at the thought of the pleasurable condition of those around him; trains of painful ideas at the thought of the reverse; and he is thus led to have an habitual desire for the one,—aversion to the other. But if pleasures, whencesoever derived, of those about him, are apt to be the cause of good to himself, those pleasures which they derive from himself are in a greater degree the cause of good to himself. If those about him are disposed to exert themselves to please him when they are pleased themselves, they are disposed to exert themselves in a much greater degree to please *him*, in particular, when it is he who is the cause of the pleasure they enjoy. A train of ideas, in the highest degree pleasurable, may thus habitually pass through his mind at the thought of happiness to others, produced by himself; a train of ideas, in the highest degree painful, at the thought of misery to others, produced by himself: and in this manner the foundation of a life of beneficence is laid.

The business of a skilful education is, so to arrange the circumstances by which the child is surrounded, that the impressions made upon him shall be in the order most conducive to this happy result. The impressions, too, which are made originally upon the child are but one of the causes of the trains which are rendered habitual to him, and which therefore obtain a leading influence on his mind. When he is often made to conceive the trains of other men, by the words, or other signs by which their feelings are betokened, those borrowed trains become also habitual, and exert a similar influence on the mind. This, then, is another of the instruments of education. When the trains signified to the child of the ideas in the minds of those about him are trains of pleasure at the thought of the happiness of other human beings, trains of the opposite kind at the conception of their misery; and when the trains are still more pleasurable or painful at the thought of the happiness or misery produced by themselves, the association becomes in time sufficiently powerful to govern the life.

The grand object of human desire is a command over the wills of other men. This may be attained, either by qualities and acts which excite their love and admiration, or by those which excite their terror. When the education is so wisely conducted as to make the train run habitually from the conception of the good end to the conception of the good means; and as often, too, as the good means are conceived, viz. the useful and beneficial qualities, to make it run on to the conception of the great reward, the command over the wills of men; an association is formed which impels the man through life to pursue the great object of desire, by fitting himself to be, and by actually becoming the instrument of the greatest possible quantity of benefit to his fellow men.

But, unhappily, a command over the wills of men may be obtained by other means than by doing them good; and these, when a man can command them, are the shortest, the easiest, and the most effectual. These other means are all summed up in a command over the pains of other men. When a command over the wills of other men is pursued by the instrumentality of pain, it leads to all the several degrees of vexation, injustice, cruelty, oppression, and tyranny. It is, in truth, the grand source of all wickedness, of all the evil which man brings upon man. When the education is so deplorably bad as to allow an association to be formed in the mind of the child between the grand object of desire, the command over the wills of other men, and the fears and pains of other men, as the means; the foundation is laid of bad character,—the bad son, the bad brother, the bad husband, the bad father, the bad neighbour, the bad magistrate, the bad citizen,—to sum up all in one word, the bad man. Yet, true it is, a great part of education is still so conducted as to form that association. The child, while it yet hangs at the breast, is often allowed to find out by experience, that crying, and the annoyance which it gives, is that by which chiefly it can command the services of its nurse, and obtain the pleasures which it desires. There is not one child in fifty who has not learned to make its cries and wailings an instrument of power, and very often an instrument of absolute tyranny. When the evil grows to excess, the vulgar say the child is spoiled. Not only is the child allowed to exert an influence over the wills of others by means of their pains, it finds, that frequently, sometimes most frequently, its own will is needlessly and unduly commanded by the same means, pain, and the fear of pain. All these sensations concur in establishing a firm association between the idea of the grand object of desire, command over the acts of other men, and those of pain and terror, as the means of acquiring it. That those who have been subject to tyranny are almost always desirous of being tyrants in their turn; that is to say, that a strong association has been formed in their minds between the ideas of pleasure and dignity, on the one hand, and those of the exercise of tyranny, on the other, is a matter of old and invariable observation. An anecdote has just been mentioned to us, so much in point, that we will repeat it, as resting on its own probability, though it is by hearsay testimony (very good, however, of its kind) by which it has reached us. At Eton, in consequence, it is probable, of the criticisms which the press has usefully made upon the system of *fagging* (as it is called) at the public schools, a proposition was lately made, among the boys themselves, for abolishing it. The idea originated with the elder boys, who were in possession of the power,—a power of a very unlimited and formidable description,—and was by them warmly supported; but it was opposed with still greater vehemence by the junior boys, the boys who were then the victims of it, so much did the expected pleasure of tyrannizing in their turn outweigh the pain of their present slavery.—In this case, too, as in most others, the sources of those trains which govern our lives are two,—the impressions made upon ourselves, and the trains which we copy from others. Besides the impressions just recounted, if the trains which pass in the minds of those by whom the child is surrounded, and which he is made to conceive by means of their words, and other signs, lead constantly from the idea of command over the wills of other men, as the grand object of desire, to the ideas of pain and terror as the means, the repetition of the copied trains increases the effect of the native impressions, and establishes and confirms the maleficent character. These are the few things we can afford to adduce upon the subject of Domestic Education.

In the next place comes that which we have denominated *Technical*. To this the term Education has been commonly confined; or, rather, the word Education has been used in a sense so unhappily restricted, that it has extended only to a part of that which we call *Technical Education*. It has not extended to all the arts, but only to those which have been denominated *liberal*.

The question here occurs, What is the sort of education required for the different classes of society, and what should be the difference in the training provided for each? Before we can treat explicitly of technical education, we must endeavour to show, in what manner at least, this question ought to be resolved.

There are certain qualities, the possession of which is desirable in all classes: There are certain qualities, the possession of which is desirable in some, not in others. As far as those qualities extend which ought to be common to all, there ought to be a correspondent training for all. It is only in respect to those qualities which are not desirable in all, that a difference in the mode of training is required.

What then are the qualities, the possession of which is desirable in all? They are the qualities which we have already named as chiefly subservient to the happiness of the individual himself, and of other men,—Intelligence, Temperance, and Benevolence. It is very evident that all these qualities are desirable in all men; and if it were possible to get them all in the highest possible degree in all men, so much the more would human nature be exalted.

The chief difficulty respects Intelligence, for it will be readily allowed, that almost equal care ought to be taken, in all classes, of the trains leading to the settled dispositions which the terms Temperance and Benevolence denote. Benevolence, as we have above described it, can hardly be said to be of more importance to the happiness of man in one class than in another. If we bear in mind, also, the radical meaning of Temperance, that it is the steady habit of resisting a present desire, for the sake of a greater good, we shall readily grant, that it is not less necessary to happiness in one rank of life than in another. It is only necessary to see, that temperance, though always the same disposition, is not always exerted on the same objects, in the different conditions of life. It is no demand of temperance, in the man who can afford it, to deny himself animal food; it may be an act of temperance in the man whose harder circumstances require that he should limit himself to coarser fare. It is also true, that the trains which lead to Temperance and Benevolence may be equally cultivated in all classes. The impressions which they are made to receive, and the trains of others which they are made to copy, may, with equal certainty, be guided to the generating of those two qualities in all the different classes of society. We deem it unnecessary (here, indeed, it is impossible) to enter into the details of what may be done in the course of technical education, to generate, or to confirm, the dispositions of Temperance and Benevolence. It can be nothing more than the application of the principles which we developed, when we endeavoured to show in what manner the circumstances of domestic education might be employed for generating the trains on which these mental qualities depend.

Technical Education we shall then consider as having chiefly to do with *Intelligence*.

The first question, as we have said before, respects what is desirable for all,—the second what is desirable for each of the several classes. Till recently, it was denied, that intelligence was a desirable quality in the great body of the people; and as intelligence is power, such is an unavoidable opinion in the breasts of those who think that the human race ought to consist of two classes,—one that of the oppressors, another that of the oppressed. The concern which is now felt for the education of the working classes, shows that we have made a great step in knowledge, and in that genuine morality which ever attends it.

The analysis of the ideas decides the whole matter at once. If education be to communicate the art of happiness, and if intelligence consists of two parts,—a knowledge of the order of those events of nature on which our pleasures and pains depend, and the sagacity which discovers the best means for the attaining of ends,—the question, whether the people should be educated, is the same with the question, whether they should be happy or miserable. The question, whether they should have more or less of intelligence, is merely the question, whether they should have more or less of misery, when happiness might be given in its stead. This has been seized, and made use of as an objection, viz. that men are seen, by daily experience, not to be happy, not to be moral, in proportion to their knowledge. It is wonderfully shallow. Hume said long ago, that knowledge, and its accompaniments, morality and happiness, may not be strictly conjoined in every individual, but they are infallibly so in every age and in every country. The reason is plain: a natural cause may be hindered of its operation in one particular instance, though in a great variety of instances it is sure to prevail. Besides, there may be a good deal of knowledge in an individual, but not knowledge of the best things; this cannot easily happen in a whole people; neither the whole nor the greater part will miss the right objects of knowledge, when knowledge is generally diffused.

As evidence of the vast progress which we have made in right thinking upon this subject, we cannot help remarking, that even when Milton and Locke wrote upon education, though both men of so much benevolence to the larger family of mankind, and both men whose sentiments were democratical, they yet seem to have had in their view no education but that of the *gentleman*: education had not presented itself, even to their minds, as a blessing in which the indigent orders could be made to partake.

As we strive for an equal degree of justice, an equal degree of temperance, an equal degree of veracity, in the poor as in the rich, so we should strive for an equal degree of intelligence, if there were not a cause which prevents. It is absolutely necessary for the existence of the human race, that labour should be performed, that food should be raised, and other things provided which human welfare requires. A large portion of mankind is required for this labour. Now, then, in regard to all this portion of mankind that labours, only such a portion of time can by them be given to the acquisition of intelligence as can be abstracted from labour. The difference between intelligence and the other qualities desirable in the mind of man, is this,—that much of time exclusively devoted to the fixing of the associations on which they depend is not necessary; such trains may go on while other things are attended to, and amid the whole of the business of life. The case, to a certain extent, is the same with intelligence; but, to a great extent, it is not. Time must be exclusively devoted to the acquisition of it; and there are degrees of command over knowledge to which the whole period of human life is not more than sufficient. There are degrees, therefore, of intelligence, which must be reserved to those who are not obliged to labour.

The question is (and it is a question which none can exceed in magnitude), What is the degree attainable by the most numerous class? To this we have no doubt, it will, in time, very clearly appear, that a most consolatory answer may be given. We have no doubt it will appear that a very high degree is attainable by them. It is now almost universally acknowledged, that, on all conceivable accounts, it is desirable that the great body of the people should not be wretchedly poor; that when the people are wretchedly poor, all classes are vicious, all are hateful, and all are unhappy. If so far raised above wretched poverty, as to be capable of being virtuous, though it is still necessary for them to earn their bread by the sweat of their brow, they are not bound down to such incessant toil as to have no time for the acquisition of knowledge, and the exercise of intellect. Above all, a certain portion of the first years of life are admirably available to this great end. With a view to the productive powers of their very labour, it is desirable that the animal frame should not be devoted to it before a certain age, before it has approached the point of maturity. This holds in regard to the lower animals: a horse is less valuable, less, in regard to that very labour for which he is valuable at all, if he is forced upon it too soon. There is an actual loss, therefore, even in productive powers, even in good economy, and in the way of health and strength, if the young of the human species are bound close to labour before they are fifteen or sixteen years of age. But if those years are skilfully employed in the acquisition of knowledge, in rendering all those trains habitual on which intelligence depends, it may be easily shown that a very high degree of intellectual acquirements may be gained; that a firm foundation may be laid for a life of mental action, a life of wisdom, and reflection, and ingenuity, even in those by whom the most ordinary labour will fall to be performed. In proof of this, we may state, that certain individuals in London, a few years ago, some of them men of great consideration among their countrymen, devised a plan for filling up those years with useful instruction,—a plan which left the elements of hardly any branch of knowledge unprovided for, and at an expence which would exceed the means of no class of a population, raised above wretched poverty to that degree which all men profess to desire. Mr. Bentham called this plan of instruction by the Greek name *Chrestomathia*; and developed his own ideas of the objects and mode of instruction, with that depth and comprehension which belong to him, in a work which he published under that name.[*] Of the practicability of the scheme, no competent judge has ever doubted; and the difficulty of collecting funds is the only reason why it has not, already, been demonstrated by experiment, how much of that intelligence which is desirable for all, may be communicated to all.[†]

Beside the knowledge or faculties which all classes

---

[*] *Chrestomathia,* being a collection of papers explanatory of the design of an institution proposed to be set on foot, under the name of the Chrestomathic Day-school, &c. By Jeremy Bentham, Esq.

[†] We mention, with extraordinary satisfaction, that an idea of education, hardly less extensive than what is here alluded to, has been adopted by that enlightened and indefatigable class of men, the Baptist Missionaries in India, for the population, poor as well as ignorant, of those extensive and populous regions. A small volume, entitled, "*Hints relative to Native Schools, together with the Outline of an Institution for their Extension and Management,*" was printed at the mission press at Serampore in 1816; and, as it cannot come into the hands of many of our readers, we gladly copy from it the following passage, in hopes that the example may be persuasive with many of our countrymen at home:

"It is true, that when these helps are provided, namely, a correct system of orthography, a sketch of grammar, a simplified system of arithmetic, and an extended vocabulary, little is done beyond laying the foundation. Still, however, this foundation must be laid, if any superstructure of knowledge and virtue be attempted relative to the inhabitants of India. Yet, were the plan to stop here, something would have been done. A peasant, or an artificer, thus rendered capable of writing as well as reading his own language with propriety, and made acquainted with the principles of arithmetic, would be less liable to become a prey to fraud among his own countrymen, and far better able to claim for himself that protection from oppression, which it is the desire of every enlightened government to grant. But the chief advantage derivable from this plan is, its facilitating the reception of ideas which may enlarge and bless the mind in a high degree,—ideas for which India must be indebted to the west, at present the seat of science, and for the communication of which, generations yet unborn will pour benedictions on the British name.

"1. To this, then, might be added a concise, but perspicuous account of the solar system, preceded by so much of the laws of motion, of attraction, and gravity, as might be necessary to render the solar system plain and intelligible. These ideas, however, should not be communicated in the form of a treatise, but in that of simple axioms, delivered in short and perspicuous sentences. This method comes recommended by several considerations: it agrees with the mode in which doctrines are communicated in the *Hindoo Shastras,* and is therefore congenial with the ideas of even the learned among them; it would admit of these sentences being written from dictation, and even committed to memory with advantage, as well as of their being easily retained; and, finally, the conciseness of this method would allow of a multitude of truths and facts relative to astronomy, geography, and the principal phenomena of nature, being brought before youth within a very small compass.

"2. This abstract of the solar system might be followed by a compendious view of geography on the same plan, that of comprising every particular in concise but luminous sentences. In this part it would be proper to describe Europe particularly, because of its importance in the present state of the world; and Britain might, with propriety, be allowed to occupy in the compendium, that pre-eminence among the nations which the God of Providence has given her.

"3. To these might be added a number of popular truths and facts relative to natural philosophy. In the present improved state of knowledge, a thousand things have been ascertained relative to light, heat, air, water, to meteorology, mineralogy, chemistry, and natural history, of which the ancients had but a partial knowledge, and of which the natives of the East have as yet scarcely the faintest idea. These facts, now so clearly ascertained, could be conveyed in a very short compass of language, although the process of reasoning, which enables the mind to account for them, occupies many volumes. A knowledge of the facts themselves, however, would be almost invaluable to the Hindoos, as these facts would rectify and enlarge their ideas of the various objects of nature around them; and while they, in general, delighted as well as informed those who read them, they might inflame a few minds of a superior order with an unquenchable desire to know *why* these things are so, and thus urge them to those studies, which in Europe have led to the discovery of these important facts.

"4. To this view of the solar system of the earth, and the various objects it contains, might, with great advantage, be added such a compendium of history and chronology united, as should bring them acquainted with the state of the world in past ages, and with the principal events which have occurred since the creation of the world. With the creation it should commence, describe the primitive state of man, the entrance of evil, the corruption of the antediluvian age, the flood, and the peopling of the earth anew from one family, in which the compiler should avail himself of all the light thrown on this subject by modern research and investigation; he should particularly notice the nations of the east, incorporating, in their proper place, the best accounts we now have both of India and China. He should go on to notice the call of Abraham, the giving of the decalogue, the gradual revelations of the Scriptures of Truth, the settlement of Greece, its mythology, the Trojan war, the four great monarchies, the advent of the Saviour of men, the persecutions of the Christian church, the rise of Mahometanism, the origin of the papacy, the invention of printing, of gunpowder, and the mariner's compass, the reformation, the discovery of the passage to India by sea, and the should possess in common, there are branches of knowledge and art which they cannot all acquire; and, in respect to which, education must undergo a corresponding variety. The apprenticeships, for example, which youth are accustomed to serve to the useful arts, we regard as a branch of their education. Whether these apprenticeships, as they have hitherto been managed, have been good instruments of education, is a question of importance, about which there is now, among enlightened men, hardly any diversity of opinion. When the legislature undertakes to do for every man, what every man has abundant motives to do for himself, and better means than the legislature; the legislature takes a very unnecessary, commonly a not very innocent trouble. Into the details, however, of the best mode of teaching, to the working people, the arts by which the different commodities useful or agreeable to man are provided, we cannot possibly enter. We must content ourselves with marking it out as a distinct branch of the subject, and an important object of study.

With respect to the education of that class of society who have wealth and time for the acquisition of the highest measure of intelligence, there is one question as to which every body must be ripe for a decision. If it be asked, whether, in the constitution of any establishment for their education, call it university, call it college, school, or any thing else, there ought to be a provision made for perpetual improvement,—a provision to make it keep pace with the human mind; or if, on the other hand, it ought to be so constituted as that there shall not only be no provision for, but a strong spirit of resistance to all improvement,—a passion of adherence to whatever was established in a dark age, and a principle of hatred to those by whom improvement is proposed;—all indifferent men will declare that such institutions would be a curse rather than a blessing. That he is a *progressive* being, is the grand distinction of man; he is the only progressive being upon this globe; when he is the most rapidly progressive, then he most completely fulfills his destiny: an institution for *education* which is hostile to progression, is, therefore, the most preposterous and vicious thing, which the mind of man can conceive.

There are several causes which tend to impair the utility of old and opulent establishments for education. Their love of ease makes them love easy things, if they can derive from them as much credit, as they would from others which are more difficult. They endeavour, therefore, to give an artificial value to trifles. Old practices, which have become a hackneyed routine, are commonly easier than to make improvements: accordingly, they oppose improvements, even when it happens that they have no other interest in the preservation of abuses. Hardly is there a part of Europe in which the Universities are not recorded, in the annals of of education, as the enemies of all innovation. "A peine la compagnie de Jesus," says d'Alembert, "commença-t-elle à se montrer en France, qu'elle essuya des difficultés sans nombre pour s' y établir. Les universités sur tout firent les plus grands efforts, pour écarter ces nouveaux venus. Les Jesuites s' annonçaient pour enseigner gratuitement, ils comptoient déja parmieux des hommes savans et célèbres, superieurs peut-être à ceux dont les universités pouvaient se glorifier; l' interêt et la vanité pouvaient done suffire à leurs adversaires pour chercher à les exclure. Ou se rapelle les contradictions semblables que les ordres mendians essuyerent de ces mêmes universités quand ils voulurent s' y introduire; contradictions fondées à peu près sur les mèmes motifs." *(Destruction des Jesuites in France.)* The celebrated German Philosopher Wolf remarks the aversion of the universities to all improvement, as a notorious thing, founded upon adequate motives, in the following terms: "*Non adeo impune turbare licet scholarum quietem, et docentibus lucrosam, et disentibus jucundam.*" (Wolfii *Logica*, Dedic. p. 2.)

But though such and so great are the evil tendencies which are to be guarded against in associated seminaries of education,—evil tendencies which are apt to be indefinitely increased when they are united with an ecclesiastical establishment, because, whatever the vices of the ecclesiastical system, the universities have in that case an interest to bend the whole force of their education to the support of them all, and the human mind can only be rendered the friend of abuses in proportion as it is vitiated intellectually, or morally, or both; it must, notwithstanding, be confessed, that there are great advantages in

---

various discoveries of modern science. Such a synopsis of history and chronology, composed on the same plan, that of comprising each event in a concise but perspicuous sentence, would exceedingly enlarge their ideas relative to the state of the world, certainly not to the disadvantage of Britain, whom God has now so exalted as to render her almost the arbitress of nations.

"5. Lastly, It would be highly proper to impart to them just ideas of themselves, relative both to body and mind, and to a future state of existence, by what may be termed a Compendium of Ethics and Morality. The complete absence of all just ideas of this kind, is the chief cause of that degradation of public morals so evident in this country.

"These various compendiums, after being written from dictation, in the manner described in the next section, might also furnish matter for reading; and when it is considered that, in addition to the sketch of grammar, the vocabulary, and the system of arithmetic, they include a view of the solar system, a synopsis of geography, a collection of facts relative to natural objects, an abstract of general history, and a compendium of ethics and morality, they will be found to furnish sufficient matter for reading while youth are at school."

Why should not the same idea be pursued in England, and as much knowledge conveyed to the youth of all classes at school, as the knowledge of the age, and the allotted period of schooling will admit?

putting it in the power of the youth to obtain all the branches of their education in one place; even in assembling a certain number of them together, when the principle of emulation acts with powerful effect; and in carrying on the complicated process according to a regular plan, under a certain degree of discipline, and with the powerful spur of publicity. All this ought not to be rashly sacrificed; nor does there appear to be any insuperable difficulty in devising a plan for the attainment of all these advantages, without the evils which have more or less adhered to all the collegiate establishments which Europe has yet enjoyed.

After the consideration of these questions, we ought next to describe, and prove by analysis, the exercises which would be most conducive in forming those virtues which we include under the name of intelligence. But it is very evident, that this is a matter of detail far too extensive for so limited a design as ours. And though education, in common language, means hardly any thing more than making the youth perform those exercises; and a treatise on education means little more than an account of them, we must content ourselves with marking the place which the inquiry would occupy in a complete system, and proceed to offer a few remarks on the two remaining branches of the subject, *Social Education*, and *Political Education*.

The branches of moral education, heretofore spoken of, operate upon the individual in the first period of life, and when he is not as yet his own master. The two just now mentioned operate upon the whole period of life, but more directly and powerfully after the technical education is at an end, and the youth is launched into the world under his own control.

Social Education is that in which society is the Institutor. That the society in which an individual moves, produces great effects upon his mode of thinking and acting, every body knows by indubitable experience. The object is, to ascertain the extent of this influence, the mode in which it is brought about, and hence the means of making it operate in a good, rather than an evil direction.

The force of this influence springs from two sources: the principle of imitation; and the power of the society over our happiness and misery.

We have already shown, that when, by means of words, and other signs of what is passing in the minds of other men, we are made to conceive, step by step, the trains which are governing them, those trains, by repetition, become habitual to our own minds, and exert the same influence over us as those which arise from our own impressions. It is very evident, that those trains which are most habitually passing in the minds of all those individuals by whom we are surrounded, must be made to pass with extraordinary frequency through our own minds, and must, unless where extraordinary means are used to prevent them from producing their natural effect, engross to a proportional degree the dominion of our minds. With this slight indication of this source of the power which society usurps over our minds, that is, of the share which it has in our education, we must content ourselves, and pass to the next.

Nothing is more remarkable in the proceedings of human nature, than the intense desire which we feel of the favourable regards of mankind. Few men could bear to live under an exclusion from the breast of every human being. It is astonishing how great a portion of all the actions of men are directed to this object and to no other. The greatest princes, the most despotical masters of human destiny, when asked, What they aim at by their wars and conquests? would answer, if sincere, as Frederic of Prussia answered, *pour faire parler de soi*; to occupy a large space in the admiration of mankind? What are the ordinary pursuits of wealth and of power, which kindle to such a height the ardour of mankind? Not the mere love of eating and of drinking, or all the physical objects together, which wealth can purchase or power command. With these every man is at bottom speedily satisfied. It is the easy command, which those advantages procure over the favourable regards of society,—it is this which renders the desire of wealth unbounded, and gives it that irresistible influence which it possesses in directing the human mind.

Whatever, then, are the trains of thought, whatever is the course of action which most strongly recommends us to the favourable regards of those among whom we live, these we feel the strongest motive to cultivate and display; whatever trains of thought and course of action expose us to their unfavourable regards, these we feel the strongest motives to avoid. These inducements, operating upon us continually, have an irresistible influence in creating habits, and in moulding, that is, educating us, into a character conformable to the society in which we move. This is the general principle; it might be illustrated in detail by many of the most interesting and instructive phenomena of human life; it is an inquiry, however, in which we must not indulge.

To what extent the habits and character, which those influences tend to produce, may engross the man, will no doubt depend, to a certain degree, upon the powers of the domestic and technical education which he has undergone. We may conceive that certain trains might, by the skilful occupation of the early years, be rendered so habitual as to be uncontrollable by any habits which the subsequent period of life would induce, and that those trains might be the decisive ones on which intelligent and moral conduct depends. The influence of a vicious and ignorant society would in this case be greatly reduced; but still, the actual rewards and punishments which society has to bestow upon those who please, and those who displease it; the good and evil which it gives or withholds, are so great, that to adopt the opinions which it approves, to perform the acts which it admires, to acquire the character, in short, which it "delighteth to honour," can seldom fail to be the leading object of those of whom it is composed. And as this potent influence operates upon those who conduct both the domestic education and the technical, it is next to impossible that the trains which are generated, even during the time of their operation; should not fall in with, instead of counteracting, the trains which the social education produces; it is next to impossible, therefore, that the whole man should not take the shape which that influence is calculated to impress upon him.

The *Political Education* is the last, which we have undertaken to notice, of the agents employed in forming the character of man. The importance of this subject has not escaped observation. Some writers have treated of it in a comprehensive and systematical manner. And a still greater number have illustrated it by occasional and striking remarks. It is, nevertheless, true, that the full and perfect exposition of it yet remains to be made.

The Political Education is like the key-stone of the arch; the strength of the whole depends upon it. We have seen that the strength of the Domestic and the Technical Education depends almost entirely upon the Social. Now it is certain, that the nature of the social depends almost entirely upon the Political; and the most important part of the Physical (that which operates with greatest force upon the greatest number, the state of aliment and labour of the lower classes), is, in the long-run, determined by the action of the political machine. The play, therefore, of the political machine acts immediately upon the mind, and with extraordinary power; but this is not all; it also acts upon almost every thing else by which the character of the mind is apt to be formed.

It is a common observation, that such as is the direction given to the desires and passions of men, such is the character of the men. The direction is given to the desires and passions of men by one thing, and one alone; the means by which the grand objects of desire may be attained. Now this is certain, that the means by which the grand objects of desire may be attained, depend almost wholly upon the political machine. When the political machine is such, that the grand objects of desire are seen to be the natural prizes of great and virtuous conduct—of high services to mankind, and of the generous and amiable sentiments from which great endeavours in the service of mankind naturally proceed—it is natural to see diffused among mankind a generous ardour in the acquisition of all those admirable qualities which prepare a man for admirable actions; great intelligence, perfect self-command, and over-ruling benevolence. When the political machine is such that the grand objects of desire are seen to be the reward, not of virtue, not of talent, but of subservience to the will, and command over the affections of the ruling few; that interest with the *man above* is the only sure means to the next step in wealth, or power, or consideration, and so on; the means of pleasing the man above become, in that case, the great object of pursuit. And as the favours of the man above are necessarily limited—as some, therefore, of the candidates for his favour can only obtain the objects of their desire by disappointing others—the arts of supplanting rise into importance; and that whole tribe of faculties which is expressed by the words intrigue, flattery, back-biting, treachery, &c., are the fruitful offspring of that political education, which a government, in which the many interests of the subject are but a secondary object, cannot fail to produce. (F. F.)

See the article EDUCATION, in the *Encyclopædia* for the discussion of various questions connected with that subject, and UNIVERSITIES, in this *Supplement*

EDWARDS (BRYAN), the well-known historian of the *West Indies*, was born at Westbury in Wiltshire, on the 21st May 1743. His father had a small paternal estate, but as this did not exceed L.100 *per annum*, he found it insufficient for the maintenance of a numerous family, and endeavoured to improve his circumstances by dealing in corn and malt. This hazardous trade proved, as it often does, only a means of more deeply involving his affairs, and he died in 1756, leaving a widow and six children in a very distressed situation. Mrs Edwards, however, had two opulent brothers in the West Indies, the eldest of whom, called Zachary Bayly, possessing a princely fortune, and being of a very amiable and generous disposition, undertook the support and education of young Edwards. He had already been placed by his father at the school of Mr Foot, a dissenting clergyman at Bristol, where he had been taught the elementary branches of education; but for some reason which he never was able to divine, that person was strictly prohibited from initiating him in any branches of classical learning. He gave a species of instruction, however, not usual in schools, and from which his pupil, probably, derived the greatest benefit. He was accustomed to make the boys write letters, or rather essays, on various subjects, such as the beauty and dignity of truth,—the obligations to a religious life,—the benefits of good education, &c. giving them, where it appeared necessary, an outline of the arguments which might be employed on the subject. When the papers were given in, he made such observations as appeared proper, insisting, at least, that they should be correct in point of grammar and orthography. These exercises gave occasion to display the superior talents of Edwards, whose powers of elegant composition already began to appear. He soon became the favourite of his master, who liberally praised these youthful performances, and often transmitted them for the gratification of his parents. They were entirely satisfied; but when the care of his education devolved on his uncle, the agent employed by him at Bristol was much surprised to find an entire deficiency in classical knowledge, and imputing the blame to the master, removed him immediately to a French boarding school in the same city. It is not said, that he acquired here any great portion of Greek and Latin, but he became master of the French language, and having access to an extensive circulating library, cultivated a taste for reading which adhered to him through the whole of his future life.

In 1759, another uncle, the younger brother of him under whose care he had hitherto been, arrived in England. He, too, was possessed of an ample fortune, became member of Parliament, first for Abingdon, and afterwards for his native town, and set up a splendid establishment in London. He appeared quite disposed to befriend young Edwards, and even took him to reside with him; but the latter observes, that after enumerating his external advantages, he had nothing else to say in favour of his uncle. What the bad qualities were, which drew forth so unfavourable a sentence, we are not informed; but in a few months they separated, and Edwards went out to his other uncle. In this friend he seems to have found every thing he could desire, the most enlightened mind, the sweetest temper, and most generous disposition. To this was added, a truly paternal regard for himself, which was returned with all the warmth of filial affection. His uncle, finding him possessed of literary talents, but deficient in classical acquirements, engaged a Mr Teale, a clergyman, and formerly master of a free grammar school, to reside in his house, and give him the instruction of which he stood in need. This choice proved most acceptable to Edwards; he found in Mr Teale a man of extensive information, and possessing considerable taste in poetry. He viewed him, therefore, as a companion rather than a teacher; but this relation between the tutor and pupil, however agreeable to both, was not favourable for instilling the dry principles of grammar and prosody. A much larger proportion of their time was spent in tasting the beauties of Dryden and Pope, and in laughing at the comic sallies of Moliere. Mr Edwards, upon the whole, acquired, during this period, small Latin and less Greek; but he continued to practise composition, both in prose and verse, and the two companions sent occasional pieces to the colonial newspapers.

The time was now coming when Mr Edwards's talents were to be exercised in a wider sphere. His uncle dying, bequeathed to him his property; and, in 1773, he became heir to the much larger estate of Mr Hume, also of Jamaica. His wealth and talents united, now entitled him to take a lead in the political concerns of the island. In 1784, he published "*Thoughts on the Proceedings of Government, respecting the Trade of the West India Islands with the United States of America.*" This was followed by a speech delivered at a free conference between the Council and Assembly at Jamaica, held on the 25th of November 1789, on the subject of Mr Wilberforce's propositions in the House of Commons concerning the Slave Trade. It was in 1793, however, that he published his great work, on which he had been many years engaged, entitled, *History, Civil and Commercial, of the British Colonies in the West Indies*, 2 vols. 4to. He begins the work by giving a view of the original inhabitants of the West Indies, their manners, institutions, and the means by which they have been so entirely exterminated. This was followed by a sketch of the revolutions through which these islands have passed since the first European invasion. He gives next a geographical and statistical description of each particular island. He treats finally, at great length, on the government, social state, and above all, the commerce, of this remarkable region. In the course of the discussion, he enters fully into its relations with the African coast and the Negro slave trade. Mr Edwards, as a great and long-resident proprietor, was almost inevitably led to be a supporter of this traffic. He reasons, however, in a liberal and candid manner on the question, and does not even attempt to deny the extent of the evils with which it was accompanied. He only insists that these evils have been overrated; and that Great Britain, by renouncing it while it was still prosecuted by the other nations of Europe, would ruin her own colonies, without doing any thing to improve the condition of the Africans. In 1796, he published, in one volume 4to, a *History of St Domingo*, an island which had excited a deep interest, in consequence of the insurrection of the slaves, and the consequent establishment of an independent Negro government. In 1801, a new addition of both these works was published, in 3 vols. 8vo, under the general title of *History of the West Indies*. A fifth edition has just issued from the press. (1819.) When Park returned from his celebrated journey, Mr Edwards, from his oral information, drew up a report of it, which was submitted to the African Society, and published in their *Transactions*. Mr Park afterwards incorporated the greater part of this into the general narrative of his *Travels*, in preparing which he availed himself much of the assistance and suggestions of Mr Edwards. It has been currently said, that this narrative was entirely written by Mr Edwards; but as this assertion has been pointedly contradicted by Park, who has elsewhere shown respectable talents for composition, it can only be understood in the limited sense which has now been stated. It appears, however, that Mr Park was induced, by Mr Edwards's influence, to give rather a more favourable view of the trade in slaves than reflection afterwards led him to sanction.

Mr Edwards, after his removal to England, took up his residence at Polygon, near Southampton; and, in 1796, became member of Parliament for the borough of Grampound, which he continued to represent till his death, which took place on the 15th July 1800. He left a short narrative of his life, which was perfixed to the edition of his history published in 1801. (B.)

EDWARDS (JONATHAN), a celebrated American metaphysician and divine, was born October 5, 1703, at Windsor, in the province of Connecticut. His family had originally emigrated from England in the reign of Queen Elizabeth. His father, Mr Timothy Edwards, was a clergyman of great piety and respectability, and by his mother he was grandson of Mr Solomon Stoddard, a noted and zealous divine of Northampton. Jonathan was accordingly reared in the bosom of Puritanism, and all his ideas were early imbued with the cast of thought, which was native to the stock from which he sprung. There was something, indeed, not a little singular in the prevailing character of religion in America in those days. A *conversion* seems to have been a regular era in a man's life, which could be fixed down to a date, as much as his coming of age or being married. A very curious document remains of Jonathan's conversion, the whole steps and progress of which he has detailed for the behoof of his children; and it is a document which, even amidst all its frequent weakness and extravagance, impresses us with a high sense of the genius and of the worth of this remarkable man. We cannot avoid giving our readers a little insight into it, especially as it contains some passages of deep feeling and sensibility, which form a striking contrast to the controversial hardness of his writings. It is full of bursts of tenderness; and, even while the subjects of his earliest meditations were the same dark doctrines, in their most tremendous form, which he afterwards defended so ably by the help of his mature reason,—amidst all the gloom which naturally surrounds them, they seem to have left upon his mind no sentiments that were not gentle and charitable. At the same time, this document affords us a distinct proof, that such doctrines take their origin, in a great measure, in peculiar circumstances of society, or of the individual mind; and since they were quite as fully impressed upon Edwards, before he was capable of any profound reasoning upon them as afterwards, the presumption is, that his early prepossessions came strongly in aid of his later conclusions.

It was in the midst of these youthful musings, that he acquired a full and firm persuasion of tenets which we will own scarcely seem to us, to be either so "lovely," or of so "good report," as the more natural sentiments of his *unconverted* state, which he gave in exchange for them. "I had a variety (says he) of concerns and exercises about my soul from my childhood; but had two more remarkable seasons of awakening, before I met with that change by which I was brought to those new dispositions, and that new sense of things that I have since had. The first time was when I was a boy, some years before I went to college, at a time of *remarkable awakening* in my father's congregation. I was then very much affected for many months, and concerned about the things of religion," &c. This state of mind, however, rather passed off; but, in his last year at college, he was visited by a severe sickness, which made him form many wise and holy resolutions, which he was afterwards for the most part enabled to keep. So far well; but now follows the grand proof of his conversion: "From my childhood up," he says, "my mind had been wont to be full of objections against the doctrine of God's sovereignty, in choosing whom he would to eternal life; and rejecting whom he pleased, leaving them eternally to perish, and be everlastingly tormented in hell. It used to appear like a horrible doctrine to me. But I remember the time very well, when I seemed to be convinced, and fully satisfied as to this sovereignty of God, and his justice in thus eternally disposing of men according to his sovereign pleasure. But never could give an account how, or by what means, I was thus convinced, not in the least imagining in the time of it, nor a long time after, that there was any extraordinary influence of God's Spirit in it, but only that now I saw further, and my reason apprehended the justice and reasonableness of it. However, my mind rested in it, and it put an end to all those cavils and objections that had till then abode with me all the preceding part of my life. And there has been a wonderful alteration in my mind, with respect to the doctrine of God's sovereignty, from that day to this, so that I scarce ever have found so much as the rising of an objection against *God's sovereignty in the most absolute sense, in showing mercy to whom he will show mercy, and hardening and eternally damning whom he will.* God's absolute sovereignty and justice, with respect to salvation and damnation, is what my mind seems to rest assured of, as much as of any thing that I see with my eyes," &c. This doctrine continued through all Mr Edwards's life, in peculiar favour with him; and he employs the whole resources of his dialectics to support it, with a full conviction that he was thereby glorifying God, and performing an important service to mankind.

In this document of Mr Edwards's early opinions, we have said, that, amidst all their horrors, there are many intimations of the natural fineness and sensibility of his spirit. The following passages are remarkably beautiful, and have about them a tone almost of pastoral, or rather scriptural poetry: "Not long after I first began to experience these things, I gave an account to my father of some things that had passed in my mind. I was pretty much affected by the discourse we had together; and when the discourse was ended, I walked abroad alone, in a solitary place in my father's pasture, for contemplation. And as I was walking there, and looked up on the sky and clouds, there came into my mind so sweet a sense of the glorious majesty and grace of God, that I know not how to express...... God's excellency, his wisdom, his purity and love, seemed to appear in every thing; in the sun, moon, and stars; in the clouds and blue sky; in the grass, flowers, trees; in the water, and all nature; which used greatly to fix my mind. I often used to sit and view the moon for a long time, and so, in the day-time, spent much time in viewing the clouds and sky, to behold the sweet glory of God in these things; in the mean time, singing forth, with a low voice, my contemplations of the Creator and Redeemer....... I used to be a person uncommonly terrified with thunder; and it used to strike me with terror, when I saw a thunder-storm rising; but now, on the contrary, it rejoiced me. I felt God at the first appearance of a thunder-storm, and used to take an opportunity at such times to fix myself to view the clouds, and see the lightnings play, and hear the majestic and awful voice of God's thunder," &c. These confessions have let us already into the inside of Edwards's mind, and there is no need to return upon them, while we pursue the account of his studies, life, and writings. There is a poetry and grandeur in some of his passages of this sort, which show a moral sublimity of genius in the midst of enthusiastic reveries, often, in inferior minds, more productive of dark and disorderly sentiments, than of sound and elevated piety. When he comes, however, to reason on his theological or philosophical tenets, he is no longer either an enthusiast or a poet; for he then proceeds with all the pertinacity and ingenuity of a hard-headed special-pleading lawyer.

He went young to Yule College, and, so early as his thirteenth year, had read Locke *On the Human Understanding*, with great delight and profit. He had a great taste for natural philosophy, but the moral and divine sciences were his chief object; and after a long residence at college, during which time he prepared himself assiduously for the ministry, he was in due form licensed to preach. In August 1722, he was invited to preach to the English Presbyterians at New York, where he continued with approbation above eight months; but as this society was too small to maintain a preacher, he returned, in the year 1723, to his father's house at Connecticut, where, for some time, he applied to his studies with much industry and perseverance; and this severe application became habitual to him, although he was of a delicate constitution. In the spring of 1724, having taken his master's degree, he was appointed tutor of Yule College, being then in his twenty-first year; an office which, notwithstanding his youth, he filled for two years with great success and reputation. In September 1726, he received an invitation from the people of Northampton in Connecticut, to become assistant to his mother's father, Mr Stoddard, to whom he was ordained colleague in his twenty-fourth year, and continued pastor of this congregation till the year 1750. During this time he married, had many children, and wrote several pious and useful treatises, chiefly suggested by the events of the times; such as his "*Faithful Narrative of the Surprising Work of God, in the Conversion of many Hundred Souls in Northampton,*" (for these, as his biographer * tells us, were remarkable times for the out-pouring of God's Spirit); but particularly a sensible and useful treatise on *Religious Affections,* in which he endeavoured to restrain the extravagance and fanaticism into which, under these strong impressions, the religion of his flock was but too apt to run. He was a most faithful and conscientious minister, but at last fell under the odium of his people, from no other cause but his anxiety for their spiritual interests. They appear, indeed, to have been a very stiff-necked generation, full of absurd whimsical vagaries on the subject of religion, but, at the same time, with very little of its spirit in their lives and conversations. They had all a voice in the election and continuance of their clergyman, and they were very ready to seize any opportunity to show their power. Mr Edwards discovered that some licentious books had got among the youth of his congregation; a fact as to which he wished some investigation to take place; and this was the first point upon which his people flew off from him. There was afterwards another point about the administration of the Holy Communion. His grandfather, Mr Stoddard, it seems, had a notion, that the administration of the sacrament was a moment which the Divine Spirit was much disposed to seize for the conversion of sinners; and that, therefore, the most notorious sinners were to be, without scruple, admitted to that holy ordinance, in the hope that this conversion would fall upon them. The result of this precious notion was, that the utmost licentiousness, mingled as it was with wild religious fancies floating in every brain, began to prevail among the people. When Mr Edwards, on his grandfather's death, got the entire charge, he endeavoured to make a change in this particular. But the outcry against him was loud and overbearing. Even his brethren of the clergy tamely gave way to it; and this excellent, able, and pious clergyman was thus driven away by the misguided flock, for whom he had laboured assiduously for twenty-four years; and at an advanced period of life, with a wife and a large family, was thrown upon the world, and the care of Providence.

His next position was at Stockbridge, in the western part of Massuchusetts Bay, where he was put at the head of a mission for converting the Indians. He was not enabled to do much as a missionary, but here he had a great deal of leisure, which he employed in writing his principal works. It was now he completed his chief treatise, on the subject of free-will; concerning the rapid execution of which, we have the following information in the Reverend Sir Henry Moncreiff Wellwood's very interesting *Life of Dr Erskine.*—"It was not till the month of July 1752, that he appears to have resumed his studies on the subject of free-will; for on the 7th of that month he writes Dr Erskine, that 'he hoped soon to be at leisure to resume his design;' and gives him another sketch of the plan of his book, in which, though there be nothing new, there is more detail than in that which he had formerly sent him. Whatever opinion (continues this able writer) may be held, with regard to Mr Edwards's argument, it must appear astonishing to those who are capable of appreciating the difficulty of his subject, that, in nine months from the date of this letter (on the 14th of April 1753), he could write Dr Erskine, that he had almost finished the first draught of what he originally intended; though he was under the necessity of delaying the publication till he knew the result of proposals which he had circulated, for printing his book by subscription. His book was published in 1754, and though he had made some progress in preparing his materials before he left Northampton, was certainly written, and nearly completed, within the time ascertained by the two letters referred to, and must be admitted to convey a very striking idea, both of his mental resources, and of his literary ardour."

In 1757, on the death of Mr Aaron Burr, Mr Edwards was chosen President of New Jersey College. He had been here, however, a very short time, when he was carried off, on March 22, 1758, in the fifty-fifth year of his age, by the small-pox. This disease was, at that time, raging in the neighbourhood. Mr Edwards, who had never had it, proposed to be inoculated, which his physicians approved of. He had the disease favourably, but a secondary fever set in, and, by reason of a number of pustules in his throat, the obstruction was such that he could not swallow the necessary medicines, and the fatal result was what we have stated. The character of Mr Edwards is that of a very primitive, self-mortified, simple, and amiable man, and affords a strong proof of the power of genuine Christian piety upon the heart in spite of the most dark and awful tenets. He was solely occupied with his professional duties and his theological studies, insomuch, as is mentioned with inimitable simplicity by the author of his life, "that he was less acquainted with most of his temporal affairs than many of his neighbours, and seldom knew when and by whom his forage for winter was gathered in, or how many milk-kine he had; whence his table was furnished," &c. Mrs Edwards, however, a most valuable and sensible woman, fully supplied his defects in these particulars. We must quote another passage from this piece of biography, which is equal in simplicity, though by no means in any thing else, to some of the exquisite biographies of Isaac Walton. After being informed that he did not permit dancing (he has a sermon against that amusement), we are told that "he allowed not his children to be from home after nine o'clock at night, when they went abroad to see their friends and companions; neither were they allowed to sit up much after that time, in his own house, when any came to make them a visit. If any gentleman desired acquaintance with his daughters, after handsomely introducing himself, by properly consulting the parents, he was allowed all proper opportunity for it, *and a room and fire*, if needed; but must not intrude on the proper hours of rest and sleep, nor the religion and order of the family."

---

* This primitive piece of biography, from which all our quotations are taken, is prefixed to a volume of sermons published after Mr. Edwards's death. Its author is not mentioned. The edition from which we quote, is printed at Edinburgh by Alexander Jardine, 1799.

Mr Edwards comes nearer Bishop Butler as a philosophical divine than any other theologian with whom we are acquainted. His style, like Butler's, is very much that of a man thinking aloud. In both these authors the train of thinking in their own minds is more clearly exhibited to us than, perhaps, by any other writer; while they show us, with great truth and distinctness, what their notions are, and how they came by them, with very little concern about the form of expression in which they are brought out. Butler, however, had a larger mind than Edwards, and was by no means so much of a special pleader. He may be, therefore, less acute, but he is more comprehensive, and gives fairer play to every opposing argument. We do not mean here to enter into any of Edwards's speculations. Both on the subject of Original Sin, and on the Freedom of the Will, he seems to us to unite a great deal too closely the views which originated, as we have seen, in no small degree, amidst his early reveries, with the infallible discoveries of divine revelation. Our notion is, that in all discussions on such subjects which have hitherto appeared, the speculatists have forgotten how little a part either of the history or the nature of man we are, in fact, acquainted with; and how ready we ever are, in laying the foundations of our theories, to place a tortoise beneath the elephant. The whole difficulty, for instance, on the freedom of the will, turns upon a puzzle in the idea of cause and effect. Perhaps this idea is far from being precise in our minds (Mr Edwards uses it very loosely in his speculations), and yet we do not scruple, in our reasonings upon it, to draw the most positive inferences from the assumptions which we lay down. We suspect, for our parts, that the true and accurate notion of causation always involves the idea of volition, and, in that supposition, to ask for the cause of volition itself is absurd. It may be very true, that we cannot *will* to do any thing without previous *thought* or *motive;* neither can we *think* without previous *existence.* But is our *existence* the *cause* of our *thinking?* Just as much as our *thinking* is the *cause* of our *willing.* We are far, however, from wishing to add our own crude conceptions to those which have been piled up upon this subject from the beginning of time to the present hour, without, we believe, doing the slightest service to the cause of moral and religious truth, or doing any thing, in short, except affording an exercise for ingenuity, and too often a handle for the most uncharitable rancour and presumptuous absurdity. Mr Edwards, with all his great powers, has, accordingly, we apprehend, done but little good to the world,—we mean as a philosopher,—for he did much good in his own day, while he was living the life of a zealous and faithful Christian minister. But it is "thus we play the fools with the time; and the spirits of the wise sit in the clouds and mock us." Exalted above all the folly of *human* wisdom, the spirit of this truly good and pious man is now, it may be, disposed to regard with some such sentiment many of his own former most severe and laborious speculations, which were carried on in the serious belief, that if "the knots of Calvinism were trimmed off, or its doctrines, in the whole length and breadth of them, were not rigidly maintained, a man could nowhere set his foot down with consistency and safety, short of Deism, or even Atheism itself, or rather universal Scepticism!"

Edwards's works consist of several volumes of sermons, printed at various times, and often reprinted in this country as well as in America. Besides these, he wrote, 1. *A Treatise concerning Religious Affections*, 1746, 8vo. 2. *An account of the Life of the Reverend David Brainerd*, 1749, 8vo. 3. *An Inquiry into the Qualifications for full Communion in the Visible Church*, 1749; intended as a vindication of his principles in the matter which occasioned his dismission from Northampton. 4. *A careful and strict Inquiry into the Modern Notion of that Freedom of Will, which is supposed to be essential to Moral Agency*, 1754. 5. *The great Christian Doctrine of Original Sin defended; containing a Reply to the Objections of Dr. John Taylor*, 1758. 6. *A History of Redemption*. 7. *Miscellaneous Observations on Important Theological Subjects*. London, 1793. 8. *Remarks on Important Theological Controversies*. Ibid. 1796. Some of these were posthumous, as were a few other tracts of less importance written by him. (v. v.)

SECTION I.—*Introductory view of the latest Publications relating to Egypt.*

The antiquities and literature of Egypt have always been considered, on account of the very early progress which its inhabitants had made in the arts of civilised life, as objects of the highest interest and curiosity, though involved in inextricable obscurity; but we have acquired, in the course of the last twenty years, and are still continuing to acquire, such additional information respecting them, as promises, if completely confirmed by future researches, to establish the whole of our knowledge respecting this marvellous country on a new and a sure foundation.

A considerable portion of the labours of the French Institute at Cairo has been communicated to the public in a work of unexampled splendour and magnificence, the ponderous *Déscription de l'Egypte*, about one half of which only has hitherto appeared. Many of the monuments brought by the British army to England have also been accurately and elegantly engraved in this country; and a variety of travellers of different nations have published accounts of their numerous observations and discoveries made in Egypt and in its neighbourhood.

The first in order of these, that it will be necessary to notice, is Mr William Hamilton's volume, entitled *Remarks on Several Parts of Turkey*. Part I. *Ægyptiaca*, 4to, London, 1809. It appears that the power of the French in Egypt having terminated in September 1801, the temporary possession of the country was at first divided between the Turks, the Mamelukes, the Arabs, and the English, a circumstance which afforded some convenience to a European traveller, although it had no tendency to enlarge the sphere of his observations. In the beginning of October, Captain Leake and Lieutenant Hayes were appointed, by General Hutchinson, to make a general survey of Egypt, and of the country beyond it, if it should be found practicable to penetrate further south. Mr Hamilton, who had resided at the British head quarters for the purpose of corresponding with Lord Elgin upon the events of the war, was now at liberty to join these gentlemen in their expedition; and the various information which, with their assistance, he collected, respecting the remains of the ancient Egyptian magnificence, bears ample testimony to the good taste, as well as to the industry and accuracy of the whole party. On account, however, of the disturbed state of the country, and of a multitude of other difficulties, both moral and physical, they were unable to proceed further south than a few hours' journey beyond Syene, to a village called Debôd, opposite to which they observed the ruins of Barembre, the Parembole of the ancients; and among these they found a Greek dedication of a temple to Isis, by Ptolemy Philometor and his queen. They collected, also, a variety of inscriptions from other parts of Egypt, to which they added drawings and descriptions of the remains of the buildings to which they belonged; and, at Alexandria, in particular, Mr Hamilton was enabled, in company with some other gentlemen, by examining the inscription on Pompey's pillar, in different positions of the sun, to ascertain the name Diocletian, as that of the emperor to whom it was dedicated; and to find some traces of the name of Pompeius, who has been shown by Mr Quatremere to have been a prefect of Egypt under that emperor. It is, however, to be regretted, that the Coptic inscriptions, which are sometimes found mixed with the Greek, have not been more generally copied by travellers, since it is only among these that we can hope to find any traces of the vernacular nomeclature of the Egyptian mythology; although, from the few specimens which have been hitherto examined, it seems probable that the introduction of the Coptic character was only coëval with that of Christianity.

Mr Badia, a Spaniard, who is supposed to have been sent into the east on the business of the French government, has published two volumes of his *Travels*, under the name of *Ali Bey*. They contain some documents relating to the recent history and present state of Egypt, but very little information respecting its antiquities.

Mr Legh and Mr Smelt visited Egypt in 1812. They extended their tour as far as Ibrim, and observed, in their way, many remains of ancient buildings, some of which were in perfect preservation; but they were unable to attain the second cataract, which was said to be three days' journey further south. At Cairo, they paid a visit to the Pasha Mohammed Ali, under whom they "found Egypt in a state of greater tranquillity than it had enjoyed for many years, a change for which it is entirely indebted to the vigorous administration of the present Pasha." It appears that soon after the English had evacuated the country, the Mamelukes were driven by their rivals into Upper Egypt; they, however, regained a momentary influence in Cairo after the deposition of Mohammed Pasha by his Albanian soldiers; but they were soon again expelled by these same troops, with whom they had formed a temporary alliance; and the present Pasha, Mohammed Ali, who had been formerly captain of a pirate boat in the Archipelago, was made chief of these insurgents, whom, according to Ali Bey, he was at first obliged to indulge in all their licentiousness; but he promised that, in a few years, it should be safe to walk the streets of Cairo "with both hands full of gold," and Mr Legh found that he had completely kept his word. He was then occupied in preparations against the Wahabees, and his intercourse with England materially assisted him in his various pursuits.

Besides some other interesting antiquities which he collected, Mr Legh obtained in the island of Elephantine a few Thebaic manuscripts, written with a chalybeate ink on skins of leather, which he has deposited in the British Museum. They appear to be principally conveyances of estates, dated at Cyrshe or Gyrshe, a place 50 or 60 miles beyond Essouan or Syene; and, though unimportant in themselves, they tend to illustrate the history of the kingdom of Nubia in the middle ages. This kingdom seems to have been almost forgotten by some late travellers and geographers, although it was formerly remarkable for having been, according to an old tradition, one of the first that embraced Christianity, even in the time of the Queen Candace, one of whose servants was baptized by St Philip (Acts viii.); and who appears to have been one of the immediate successors of the Candace, mentioned by Strabo, as having attacked the province of Egypt, and having been conquered by Petronius in the time of Augustus. The kingdom of Nubia extended as far north as Syene, which continued to be the boundary of the Mussulman power in the tenth century, and probably much later. To the south it originally comprehended Ethiopia, its capital, Meroe, being placed in latitude 17°, on an island in the Nile, or rather on a peninsula formed by its principal branches. Candace had also a palace at Napata, which Pliny makes about 500 Roman miles beyond Syene, and 360 short of Meroe. In the seventh century, the Nubians seem nominally to have been made tributary to the Arabs; but they remained, in fact, almost wholly independent of them in their government, and their religion was entirely subjected to the spiritual direction of the patriarchs of Alexandria. Early in the tenth, the Nubians attacked Syene, not as rebels, but as legitimate enemies. They were, however, repulsed soon afterwards. A little later, we find that George, king of Nubia, was a mediator between the king of Abyssinia and the patriarch, whom he persuaded to send bishops from Alexandria into Ethiopia. In the eleventh century, Solomon, king of Nubia, abdicated in favour of his nephew George, and retired to a monastery, within three days' journey of Syene; whence he was brought by the Saracens to Cairo, and there treated with great attention as a sort of state prisoner. It is also said, that a king Cyriac once raised 100,000 men to assist the Christians against the Mussulmen; but the magnitude of the number renders the whole story more than doubtful. We learn from Hartmann's notes on Edrisi, that Abulfeda in the fourteenth century, and Bakui in the fifteenth, spoke of the Nubians as still Christians; and it seems highly probable that they continued to exercise their religion till about the time of Sultan Selim, in the beginning of the sixteenth century, if not still later; for Vansleb, who was at Siut in 1673, tells us, that the churches were then still entire, though they were shut up. Christianity having become completely extinct for want of pastors. He gives us the names of seventeen bishopricks, which had constituted three provinces; the first province he calls *Maracu*, and attributes to it the bishopricks of *Korta*, *Ibrim*, *Bucoras*, *Dunkala* or *Dungala*, *Sai*, *Termus*, and *Scienhur*; the second province seems to hold a middle place: and, in the third, he mentions *Soper* as the capital of the kingdom, without noticing Nuabah, which is the name given to the metropolis by the Arabic authors. D'Herbelot, who died in 1695, speaks of a patriarch still resident at Dungola, and appointed by the patriarch of Alexandria. There can, at any rate, be little doubt that the "King John," mentioned in the manuscripts of Gyrshe as a Christian, must have been a king of Nubia, and rather a predecessor of the Mek of Dungola, than a Greek Emperor, whose authority was probably never acknowledged in this country, and least of all when Egypt was in the possession of the Arabians. (Strabo, Book XVII. Pliny, Book VI. Chap. xxix. *Hist. Byzant.* Vol. XXI. *Ancient Universal History*, fol. Vol. VII. *Modern Universal History*, Vol. I. Vansleb, *Hist. de l'Egl. d'Alexandrie*, Par. 1677, p. 29. D'Herbelot, *Bibl. Orient.* *Narrative of a Journey in Egypt, and the Country beyond the Cataracts.* By Thomas Legh, M. P. 4to. Lond. 1816. *Sepulchral Inscriptions from Nubia*, Archaeologia, XIX. p. 169.)

The remains of the churches mentioned by Vansleb were observed, in many parts of Nubia, by Captain Light of the Royal Artillery, covered generally with paintings of scriptural subjects, and not uncommonly appearing to have been originally built for pagan temples. The Pasha of Egypt, he says, "was named as sovereign" of the country, "in all transactions" between Cairo and Assouan; beyond this, as far as Ibrim, which was the extent of his expedition, "the reigning Sultan Mahmoud was considered as the sovereign," though the neighbouring "cashief's power was plainly feared more." At Dakki Captain Light found the name of Hermes inscribed as that of the deity to whom the temple situated there must have been dedicated; and it will be interesting to inquire if any hieroglyphics can still be found on this remarkable edifice, which will bear a similar interpretation. (*Memoirs relating to European and Asiatic Turkey*. Edited by R. Walpole, M.A. 4to. Lond. 1817. P. 402, 465.)

Captain Light has more recently published a separate volume of his *Travels*, 4to, London, 1818. He informs us, that after the expulsion of Mohammed Pasha, two others were elected by the troops to the same dignity, each of whom remained in power a few weeks only. The last of them had appointed Mahommed Ali as his general, to command an expedition against the Mamelukes, but having succeeded in checking the enemy, the victorious general returned to expel and take place of his master. This remarkable person was originally a Thracian; and he has certainly given sufficient proofs of the "vigour" of his character in his transactions with the Mamelukes, with whom he concluded a treaty of alliance against the Wahabees; for when they had sent the stipulated force of 1500 men to co-operate with him, he put to death every man of them in a single morning. He succeeded, however, in rescuing the holy cities from the power of the Wahabees, and the possession of the keys of these cities ostensibly ob-

tained him the favour and countenance of the Porte, notwithstanding the general insubordination of his proceedings.

Mr Walpole's collection contains also some older papers of the late Mr Davison, who was British consul at Algiers, and accompanied Mr Wortley Montague to Egypt in 1763. Mr Davison discovered in the great pyramid, a room before unknown, immediately over the chamber which contains the sarcophagus; and he descended the three successive wells, to the depth of 155 feet. He also describes the catacombs of Alexandria, which seem to have been principally employed by the Greek inhabitants of that city. The same volume contains a very interesting account of the customs and manners of modern Egypt, from the journal of Dr Hume.

A considerable addition has been made to our knowledge of the geography of Egypt, by the publication of Lieutenant Colonel Leake's accurate and elegant map of that country, comprehending also a sketch of Nubia, as far as the southern cataract, which appears to be the limit of the existing remains of antiquity. Besides the results of his own personal survey, Colonel Leake has employed the observations of the French astronomers for the determination of the situation of the different places; and, with respect to the remoter parts, he has had the advantage of consulting the manuscript papers of the late lamented Mr Burckhardt, who unhappily fell a victim to a dysentery at Cairo, in October 1817, after having obtained, by a long residence in the country, under the name of Shekh Ibrahim, an intimate acquaintance with every thing that could have tended to facilitate the further prosecution of his projected expedition into parts of the continent still more remote. Besides the ruins of Greek churches, scattered throughout this country, the principal points of Nubia, which are remarked as exhibiting remains of still greater antiquity, are the Parembole of the Itinerary of Antonine, near Debod, and Tzitzi, now Klitsie, both of which had been visited by Colonel Leake and Mr Hamilton; Kardassy or Gartaas; Taphis and Contra Taphis, now Tafa; Kalabshe, the ancient Talmis; Merowan, the ancient Tutzis, near Gyrshe; Pselcis, now Dakki, and Corte, still Korti; Maharraka, supposed to be the Hierosycaminon of the Itinerary, and which may, very possibly, have been the Maracu mentioned by Vansleb as an archbishoprick; Seboua; Hasséya; Derr; Ibrim, the Premnis of the ancients; Ebsámbal, perhaps the Aboccis, with its two temples, still better known by the labours of the active and ingenious Belzoni; Beyllany, or rather Fereyg; Serra, probably Phthuris; Sukkoy, perhaps Cambusis; Samne, not improbably the Acina of Nero's spies; Amara, possibly Stadysis; and Soleb, not far short of the southernmost cataract, where the author is disposed to place the Napata of the ancients, in latitude about 19¼°: a situation which would agree very well with the distances of Napata from Syene and from Meroe; but it is impossible to admit that this cataract can be so far south as even 20°, consistently with the testimony of other geographers respecting the latitudes of Mosho and Sukkot; and, indeed, the course of the river is laid down more nearly north and south than the description of Burckhardt requires. We may, however, expect much information on this subject, from the observations which have been more recently made in the lower parts of Nubia, by Captain Corry of the Navy, who has visited them in company with his brother Lord Belmore. Latest Publications.

The *Quarterly Review* has afforded us, in several late numbers, a highly interesting and gratifying detail of the operations and discoveries, which have been conducted in Egypt, by several of our spirited and enterprising countrymen. Among these Mr Bankes has proceeded the furthest south, in the steps of Mr Burckhardt, and has made collections and drawings of a great number of striking remains of antiquity, (*Quarterly Review*, No. 31); and he has sent home to this country a variety of statues and bas reliefs, as well as large manuscripts on papyrus, in the epistolographic character. Mr Salt has been indefatigable in his exertions, and he has most fortunately found an assistant of Herculean strength of body, and of proportional energy of mind, in the person of Mr Belzoni. The head called a young Memnon, now in the British Museum, which weighs eight or ten tons, and which is one of the very finest specimens of Egyptian sculpture now in existence, was a joint present of Mr Salt and Mr Burckhardt; and Mr Belzoni has the merit of having conducted the very difficult operation of bringing it down to the Nile. Mr Hamilton has conjectured that it may have belonged to the statue described by Philostratus as a Memnon of great beauty (*Q. R.* No. 36); but the remaining fragment of the hieroglyphical inscription agrees better with the name of another sovereign, apparently of the same family, who is represented in several other magnificent monuments at Thebes and elsewhere.

Captain Caviglia, the master of a mercantile vessel in the Mediterranean, has exerted himself with singular activity and perseverance in examining the interior of the great pyramid of Cheops. After having retraced the forgotten steps of Mr Davison, he succeeded in pursuing the principal oblique passage 200 feet further downwards than it was before practicable, and in discovering at this point a communication with the well, which descends from the floor of the upper chamber. This communication affording him a freer circulation of air, he was enabled to proceed 28 feet further in the passage, when he found that it opened into a spacious chamber, 66 feet by 27, but of unequal height, immediately under the centre of the pyramid, which Mr Salt supposes to have been the place of the THECA, or sarcophagus, mentioned by Strabo as situated at the end of the oblique passage, though at present no sarcophagus is to be found in it. The floor is elevated 30 feet above the level of the Nile, so that the water could never have flowed into this part of the pyramid, to surround the tomb of Cheops, as Herodotus imagined. Some passages leading out of this chamber appear to terminate abruptly, without opening into any others. The dimensions of the upper chamber, which still contains a sarcophagus, are only 35½ feet by 17¼, and 18¾ high.

In six pyramids which have been opened, the principal passage preserves the same inclination of about

26° to the horizon: but if this construction was intended to facilitate the observation of the pole star, as has been conjectured, it was at least extremely ill contrived for the determination of time, on account of the very slow apparent motion of that star. In a small pyramid, south of that of Mycerinus, two chambers were found, but both were empty.

Captain Caviglia proceeded to examine a number of detached mausoleums, more or less dilapidated, in the neighbourhood of the pyramids: he found their embellishments chiefly in the style of the Theban catacombs; and they sometimes contained images too large to have been brought in through the doors or windows. Some of the stones with sculptures were placed upside down; and it was conjectured that these might possibly have been portions of the original casing of the pyramids, which is said to have been sculptured, but which is now fallen down.

His next undertaking was the very arduous task of digging away the sand in front of the great sphinx; a share of the expenses of this labour, which amounted to eight or nine hundred pounds, being contributed by Mr Salt and some other gentlemen. The body of the monster is principally formed out of the solid rock; the paws are of masonry, extending forwards fifty feet from the body: between them were found several sculptured tablets, so arranged as to constitute a small temple or chapel, and further forwards a square altar with horns, which seems to have been employed for burnt offerings. Several little lions, painted red, which had been placed on the neighbouring walls, are also among the antiquities which Captain Caviglia has very liberally presented to the British Museum, as a testimony of respect to the nation whose flag had formerly protected him in his voyages.

Mr Belzoni, at his own risk and expense, succeeded, after many fruitless efforts, in discovering the entrance into the second pyramid of Chephren, in which Herodotus had asserted that there were no chambers. The passage, descending at first obliquely from the north side, proceeds afterwards horizontally to the principal and central chamber, which measures 46 feet by 16, and is 23½ high, containing a sarcophagus of granite, with some bones, which, from a specimen brought over by Major Fitzclarence, have been ascertained to be those of a bullock. An Arabic inscription testifies that the pyramid had once been opened in the presence of the "Sultan Ali Mahomet the First, Ugloch," who may possibly have been the Ottoman Emperor, Mahomet the First, in the beginning of the fifteenth century. (*Quarterly Review*, No. 36, 37, 38.)

Among the Theban catacombs, Mr Belzoni has discovered six new tombs; the most remarkable of them, which, with all its galleries, is 309 feet long, he calls the tomb of Apis, from having found the mummy of a bullock in one of its chambers. In another apartment was a magnificent sarcophagus of white alabaster, almost as transparent as crystal; and the whole excavation, sculptured and painted in the most finished style of art, was found in the most perfect preservation. Mr Salt observes, that the colours are generally pure and brilliant, but intermixed with each other nearly in the proportions of the rainbow, and so subdued by the proper introduction of blacks, as not to appear gaudy, but to produce "a harmony that in some of the designs is really delicious." Mr Beechey, a son of the celebrated painter, professes himself, in a private letter, to be completely fascinated with the effect of these combinations. "One would think it was in Egypt," he observes, that "Titian, Giorgione, and Tintoret, had acquired all that vigour and magic of effect, which distinguishes them so remarkably from all other painters, in point of arrangement, and principally in the happy disposition of their darks. The new tomb," he continues, "lately discovered here by Mr Belzoni, is about to be transferred by him from Thebes to London. Belzoni has made moulds of every individual object in the tomb; accurate drawings of the whole have been executed on a small scale; the greater part are already finished, and coloured by a young Italian of the name of Ricci, whom Belzoni has employed for that purpose. The tomb will be built on the same scale with the original, and will be seen by candle light; so that the effect cannot fail to be precisely that of the excavation itself."

In Nubia the spirit and perseverance, with which the little band of excavators pursued the attempt to penetrate into the temple of Ebsambal, were not less worthy of admiration. Mr Belzoni and his servant, accompanied only by Mr Beechey, were abandoned on some futile pretence by the Arab workmen whom they had employed, and were unable to procure for many weeks any other food than durra or millet; they had resolution, however, to proceed with their enterprise as manual labourers, and they were at last amply rewarded for their perseverance. In front of the temple there were four colossal statues, sixty feet high, one of which had been thrown down; but it was only after digging for three weeks through 150 feet of sand, that our adventurers succeeded in entering the temple, consisting of fourteen chambers and a great hall, cut out of the solid rock, and ornamented with sculptures, superior, in point of execution, to the greater part of those which are found in Egypt; besides eight colossal statues thirty feet high, which are placed in the hall. Mr Belzoni also found at Thebes a colossal head and arm, supposed to have belonged to a Horus; and his lady discovered, during his absence in Nubia, a fine statue of white marble, supporting a ram's head on its knees.

Though Burckhardt's untimely end interrupted his further progress in Africa, yet with respect to Nubia his observations were complete, and he had himself prepared his journals for publication, in a form which does equal credit to his diligence and judgment in observation, and to his candour and good taste in the simple and elegant narration of that which he has observed. He informs us, that the tragedy of the Mamelukes was not confined to Cairo; but that 400 more of them were decoyed out of the mountains near Assouan, and fell victims, together with 260 of their slaves, to the treachery of Ibrahim Bey, the son of the Pasha.

It appears that the Nile, between the first and second cataracts, runs chiefly through a country of sandstone, and is navigable throughout this extent; but at the cataract of Wady Halfa, a little above Ebsambal, the sandstone terminates, and the district of granite and other primitive rocks begins, extending a hundred miles further upwards; and in this space the course of the river is interrupted by frequent shallows and small falls. The roaring of the fall at Wady Halfa, sometimes called by way of distinction Jenadel, or the cataract, may be heard at the distance of a mile or two; but the part of the river that falls is only about 20 yards over: there are, however, three falls in succession, and the neighbouring scenery is very romantic. Immediately beyond this country is Kolbe, the principal place in the district of Sukkót, for there is no town of that name: then the island Say, probably the Sai of Vansleb; and 450 miles above Assouan, according to Mr Burckhardt's reckoning, is Tinareh, in the district of Mahass, the furthest point to which he penetrated, within 15 or 20 miles of the remotest cataract, and a day and a half's journey only from Mosho, by the shortest road. The country through which he passed is supposed to contain a population not exceeding 100,000, and is governed by three Kashefs, who are brothers, and tributary to Egypt, but inclined to favour the Mamelukes, who seem to be pretty firmly established in the neighbourhood of Dongola: *Hassan* Kashef lives principally at Derr; his brothers farther south. At Mahass a series of more than 20 little kingdoms begins, which extend to Sennaar; their kings are independent, but have scarcely the power of life and death; the people are generally slave merchants, and those of Mahass are the nearest that send caravans to Cairo. At Mosho begins the kingdom of Dongola; and near it is the island of Argo, a long day's journey in length, with a brick castle in it. There are many other islands in the course of the river through Dongola, which extends for five days' journey; the country is celebrated for a very fine breed of horses, like the Arabian, but much stronger, and fed, as Bruce observed of the horses in the same neighbourhood, on straw only. The city of Merawe, singularly resembling the ancient Meroe in name, is the metropolis of the Sheygya Arabs, beyond Dongola, and is remarkable for schools, of high reputation, and particularly celebrated for their penmanship. These Arabs ride, like their distant neighbours the Abyssinians, with a toe *only* in the stirrup.

The languages spoken in Nubia are the Kensy and the Nouba, the former being confined to the northernmost parts of the country: these languages somewhat resemble each other, but they differ essentially from the Arabic, although the people are supposed to be the descendants of Bedouin Arabs, who spread from the east in the middle ages, with the exception of a few of the original inhabitants, who remain about Tafa and Serra, having become Mahometans. However this may be, it is certain that the languages exhibit no traces whatever of any dialect of the old Egyptian; and this circumstance affords a very strong argument in confirmation of the author's assertion, that the Christians had in general been expelled from Nubia before the time of Sultan Selim; the three garrisons of Bosnian soldiers, whom this prince established, in Assouan, Ibrim, and Say, having been sent by the express invitation of one of the rival factions of Arabs, who occupied the country, and remaining still distinct from the rest of the population, and being governed by their own Agas. We can only reconcile these facts with the testimonies in favour of the existence of Christianity in Nubia down to about the same time, by supposing that its extinction must have been gradual, and that the Thebaic language, and the ancient religion of the country, dwindled away by degrees, not "for want of pastors" only, but from the hostility of the Arabian intruders.

A concise but clear and satisfactory description of the various temples, noticed in Colonel Leake's map, is inserted in Mr Burckhardt's relation: and he conjectures that the order of their antiquity is nearly this: 1. Ebsambal; 2. Gyrshe; 3. Derr; 4. Samne; 5. Ballyane; 6. Hasseya; 7. Seboua; 8. Aamara and Kalabshe; 9. Dakke and Maharraka; 10. Kardassy; 11. Merowau; 12. Debot; 13. Korty; and, 14. Tafa. The small temple at Ebsambal has a head bearing a temple for the capital of its columns, like those at Dendera, but with a lock of hair hanging down on each side. The statues before the great temple, which is supposed to have been dedicated to Osiris, are of remarkably fine forms. In a small temple at Kalabshe there are some good historical sculptures of a victory over the southern countries, beyond Meroe. But the sculptures at Dakke Mr Burckhardt thinks superior to any others of the Egyptian school, and such as might have been considered as fit ornaments for a Grecian building. In a small temple at Samne, there is still an image with the attributes of Osiris, and there are figures of a Paamyles on the walls.

Mr Burckhardt has given us several Greek inscriptions, many of which had been copied by Captain Light a little differently. One of these begins with "*This is* the homage of *Caius* Cassius Celer;" not *Vulsilius*, as it had been read from Captain Light's manuscript. At Maharraka, the writer of one inscription has very benevolently included "the reader" in his petition, for a blessing from "Isis, the goddess with ten thousand names, and from the sun Sarapis." At Kardassy, an inscription dated under the Philips, the successors of the emperor Gordian, records the munificence of Psentuaxis, who gave to the temple "twenty pieces of gold in his first priesthood, and thirty in his second." A Thebaic tombstone, lying at Assouan, seems to contain only these words: "J̅S̅+C̅H̅T̅. This day, in memory of the late John Panokaë. Indict. xvi. 15. Mechir 6." In fact, there is scarcely any trace of the old Egyptian language to be found in any existing monument, employed upon any other occasion than for the most unimportant memorials of the most insignificant personages.

An article has lately appeared in one of the French journals, announcing the discovery of a ruined city, situated a few leagues from the Red Sea, by a young French traveller, Mr Cailliaud, nearly in the latitude of Assouan, and called by the Arabs, Sekelle. It has still many temples, palaces, and private houses standing, so that it may in some respects be compared to Pompeii: the architecture is Greek, with some Egyptian ornaments; several inscriptions prove that it was built by the Ptolemies; and one of the temples was evidently dedicated to Berenice. The situation agrees sufficiently well with that of the ancient city Berenice, so called in honour of the mother of Ptolemy Philadelphus, notwithstanding that several ancient authors agree in describing this city as a port on the Red Sea; for the city may easily have been at some little distance from a harbour bearing the same name; and no other town of any magnitude seems to have existed in the neighbourhood. It was through Berenice, according to Pliny, that the principal trade of the Romans with India was conducted, by means of caravans which reached the Nile at Coptus, not far from the point at which the present shorter route by Cosseir meets the river; and by this channel it is said that no less than L. 400,000 of Roman money was sent to India, while merchandises were returned, that ultimately sold for a hundred times as much. Mr Burckhardt seems to have heard some vague reports respecting these ruins; but it was reserved for Mr Cailliaud to obtain ocular evidence of their existence, and of their magnitude.

While so much has been done abroad for the recovery of the lost treasures of Egypt, it appears that no less labour has been silently employed in the pursuit of the investigation at home: and it seems to have been partly with a view to perpetuate the continuance of these efforts, that an association has been formed in London, of which the first and immediate object is merely to insure the preservation, and to facilitate the study of all that remains of Egyptian literature, by making a collection of drawings of all the hieroglyphical inscriptions in existence, and printing them lithographically, in a form most convenient for reference and examination, under the title of *Hieroglyphics, collected by the Egyptian Society*. The plates, which have already been executed, do credit to the manipulation of Mr Ackermann's press, as well as to the extreme neatness and accuracy of the draughtsman who has been employed on them. They can scarcely be said to have been published, as they are only to be distributed among a limited number of subscribers; but as they are to be presented to several public libraries, in different parts of Europe, they may be consulted by the general reader without difficulty.

In the midst of all the zeal and activity displayed by our countrymen who have travelled, or who are resident, in Egypt, it is greatly to be deplored that their attention has not yet been turned to an object, which is paramount to all the rest in its importance, for the substantial advancement of our acquaintance with the ancient history and literature of the country; that is, the recovery of the lost fragments, or of some of the duplicates of the "trilinguar," or rather trigrammatic STONE of ROSETTA; a monument which has already enabled us to obtain a general idea of the nature and subject of any given hieroglyphical inscription, by pursuing the investigations already carried to an unexpected extent by an anonymous author, whose interpretation was communicated to the Antiquarian Society by Mr ROUSE BOUGHTON, together with copies of some fragments of manuscripts which this gentleman had brought from Egypt. (*Archæologia*, Vol. XVIII. p. 61. *Museum Criticum*, No. VI. and VII.) Mr DE SACY, and more especially Mr AKERBLAD, had made some progress in identifying the sense of the several parts of the second inscription of the stone; but they had scarcely at all considered the sacred characters, and it was left for British industry, to convert to permanent profit a monument, which had before been a useless though a glorious trophy of British valour.

We must recollect, that every analysis of an unknown object of this nature, must unavoidably proceed more or less by the imperfect argumentation sometimes very properly called a circle, but which, in such instances, may be more aptly compared to a spiral, or to an algebraical approximation; since, by assuming certain incorrect suppositions, not too remote from the truth, we may render them, by means of a continual repetition of the calculation, more and more accurate, until at length the error is rendered wholly inconsiderable; and in this manner we often satisfy the conditions of a problem, which it would be impracticable to solve by a more direct method. A process thus tedious and laborious, however, loses the greatest part of its interest when the solution is obtained; and it is no longer necessary to explain in detail every step through which it has passed. The deciphering of the Rosetta stone is fortunately in great measure independent of any hypothesis of this kind extraneous to itself; and the Greek text affords at once the first approximation for beginning the process; but, in order to extend the inquiry to other objects, a variety of authorities must be compared and appreciated; we must select from the Greek authors an abstract of the religious superstitions, and of the civil ordinances of the Egyptians; but it will be necessary, in making this selection, to have some regard to the results which have been obtained from an examination of the principal hieroglyphical monuments still extant, in order that we may avoid the confusion which would be the necessary consequence of adopting indiscriminately the whole mass of contradictory matter, which various mythological authors have collected or invented upon the subject; and considering how absurdly and monstrously complicated the Egyptian superstitions really were, it becomes absolutely essential to separate that which is most fully established, or most generally admitted, from the accidental or local varieties, which may have been exaggerated by different authors into established usages of the whole nation, and still more from those which have been the fanciful productions of their own inventive faculties. Unfortunately, by far the greater number of the existing monuments of Egypt, are of a mythological nature; so that their pantheon, or rather pantherion, acquires an interest altogether foreign to its real character, on account of the utility of a general knowledge of the subject, in developing the nature of the language employed. The accounts which have been preserved, of the customs and civil ordinances of the country, are still more discordant than those which relate to their deities; but they may still, in some instances, be illustrated from monuments which remain in existence. Respecting the early history and chronology of Egypt, we can do little more than appreciate the various degrees of plausibility of the different fables that have been related, and the comparative credulity of the authors who have appeared to believe in them; for hitherto no hieroglyphical records have been discovered, which can afford as much assistance in this department of the investigation; though it is by no means impossible that a continued series of the sovereigns of Egypt, from the earliest times, may have been chronicled in more than one of the innumerable multitude of inscriptions hitherto uncopied and unexamined.

SECTION II.—*Pantheon of Egypt.*

In the selection of authorities respecting the principal deities worshipped by the Egyptians, it will be most convenient to consider the respective personages in their chronological, or rather genealogical order, as far as any evidence can be obtained to ascertain their places in the mythological system.

1. AGATHODAEMON, *Cneph*, or *Chnuphis*, appears to be the oldest representative of the divine power admitted by the Egyptians, although his attributes are not distinctly ascertained, except as the parent of Phthah, whose origin is referred, in the works of the spurious Hermes, to an egg of *Cneph*, or *Emeph*, which is perhaps the Coptic IHHNIFI, *genius of spirit*. Even before this Cneph, we are told of the existence of an *Eicton* or *Icton*, which has been supposed to mean IHHTHO, *genius of the whole world;* but this seems to have been a sort of chaos, and the personification is not generally admitted. Eusebius makes Cneph distinctly synonymous with Agathodaemon; and this interpretation seems to identify the term with the *Cnuphis*, of whom Strabo mentions a temple in Elephantine; since IHHNUFI would naturally mean *good genius*, the word NUFI occurring frequently in other compounds. In a Greek inscription lately brought to the British Museum, the emperor Nero is called the "good genius" of the world; and the winged globe hovering over the inscription, seems to be allusive to this piece of flattery but the Chnuphis, or Chnumis of the amulets of later times, is a serpent or a dragon raising itself on its tail, having rays about its head, and surrounded with stars. The name of Agathodaemon is inserted by Manetho among the fabulous kings, immediately before Cronus.

2. The same authority attributes a still higher antiquity to PHTHAH, whom it places as the first of the fabulous kings of Egypt; and he is universally considered as the great ancestor of the other deities, and is especially called the father of the sun, as we learn from various chronologers, and from Callisthenes and others. He seems to have been a personification of the creative, and perhaps of the generative power, designated under the character of a workman, or an architect. He is sometimes compared to Prometheus, as the discoverer of fire; but Hephaestus, or Vulcan, is his common representative in the Greek and Roman mythology; although it must always be remembered, that BETWEEN THE IMAGINARY PERSONAGES OF DIFFERENT NATIONS THE IDENTITY MUST NATURALLY BE ACCIDENTAL AND IMPERFECT. Cicero and Eusebius mention Phthah as the same with Vulcan; and Eratosthenes, on the authority of the Egyptian priests, interprets MOEPHTHA, *Philephaestus*, or *loving Vulcan*, which in Coptic would be exactly expressed by MAIPHTHAH, as MAISON is *loving a brother*. Mr Akerblad quotes, from a Coptic sermon of Sinnethi, the words, "Hephaestus, who is Ptah;" and this remarkable passage proves, as he justly observes, how much Jablonsky was mistaken in his orthography of *Phthash*, on which he founded one of his fanciful etymologies.

3. NEITH, the Minerva of the Egyptians, had a celebrated temple at Sais, in which was the well-known inscription on the goddess of universal nature, whose offspring, in the translation of the inscription, as preserved by Proclus, is said to be the sun. It seems, therefore, natural to call Neith the wife of Phthah; as Plato also observes, that arts were invented by Vulcan and his wife; but we are told, that Neith is to be considered as both male and female. The name is mentioned by Plato as synonymous with Minerva, and Eratosthenes explains Nitocris, Minerva the victorious.

4. RE, or PHRE, *the Sun*, otherwise called *On*, is mentioned by Manetho as the son of Vulcan. He married Rhea, and, having discovered her infidelity, condemned her to bear no offspring on any day or any night of the whole 360 that then made the year. Plutarch says, that he was represented by a young child rising out of a lotus; but this emblem is more probably attributable to Horus, who is another of the forms of the solar power, and is sometimes improperly confounded with Apollo. The word *Phre* is often found in Greek letters on the amulets, accompanied by emblems of the sun.

5. RHEA, the wife of the Sun, may perhaps have derived her name from *Re;* she appears to be identical with the *Urania*, or female Heaven, of Horapollo, the Coptic PHE being feminine. Jablonsky makes Rhea the same with Athor, but he adduces no sufficient authority for the opinion. She is said to have been familiar both with Cronus and with Thoth; and Diodorus calls her the wife and sister of Cronus.

6. IOH, *the Moon*. Plutarch tells us that Hermes played at dice with the Moon, probably as presiding over the calendar, in order to gain a time for the birth of Rhea's children, and to evade her husband's curse; so that the Moon must be considered as one of the oldest deities. The Egyptian name being masculine, the Moon can scarcely have been worshipped as a goddess; and whatever relation may have been imagined to exist between Isis and the lunar influence, the two deities were certainly not identical.

7. APOPIS, a brother of the Sun, is mentioned by Plutarch as having made war against Jove. But the Jupiter of Manetho stands much later in the list, the order being Vulcan, the Sun, Agathodaemon, Cronus, Osiris with Isis, * *, Typhon, Horus, Ares, Anubis, Hercules, Apollo, Ammon, Tithoes, Sosus, and Jove; the last nine being denominated semigods.

8. CRONUS, or *Saturn*, is only known from his connexion with Rhea, the wife of the Sun. His

character probably bore some relation to a personification of Time and Antiquity.

9. Thoth, *Theuth*, or *Taaut*, one of the most celebrated of the Egyptian deities, is sufficiently identified with Hermes or Mercury, by the testimony of a variety of authors. Diodorus mentions him as the scribe, or secretary, and privy counsellor of Osiris. He is generally considered as the inventor of letters, and of the fine arts. Plutarch and Horapollo observe, that he was typified by the ibis, which was sacred to him. Plutarch also says, that he had one arm shorter than the other.

10. Osiris, properly Oshiri, meaning in Coptic *energetic*, or *active*, which is precisely one of Plutarch's interpretations of the name, was the deity most universally adored throughout Egypt, and possessing the principal attributes of Bacchus, Adonis, and Pluto; besides being often compared to the Nile, and sometimes to the Sun. He was genealogically considered as the son of the Sun and of Rhea: at his birth, on the first of the supplementary days of the calendar, a voice was heard, proclaiming that he was Lord of all. He married his sister Isis, and, according to Diodorus, left her to govern his kingdom during his military expeditions, resembling those of Bacchus; being accompanied by Pan, Hercules, and Macedo, having a ship which was the prototype of the Argo of the Greeks, with Canopus for his pilot. He was at last treacherously shut up alive in a coffin by Typhon, aided by seventy-two conspirators, together with an Ethiopian queen Aso. The coffin, being thrown into the Nile, was carried to one of its mouths, and there left on shore; it became afterwards inclosed in the trunk of an erica, which grew round it, and which constituted one of the columns of King Malcander's palace: but the body escaped from its confinement, and was found by Typhon as he was hunting: he divided it into fourteen parts, which were afterwards found, scattered in different places, by Isis, and buried separately. Orisis, however, returned from the dead, to console his wife, and to conduct the education of his son Horus. There was a mystery in his identification with Pluto, of which the old authors affect to speak with reverence. His dress was generally white, but sometimes black. He is represented as carrying a whip, which is supposed to be intended for the punishment of Typhon. Plutarch says, that he is typified by a hawk, and denoted hieroglyphically by an eye and a sceptre.

11. Arueris, a twin-brother of Osiris, and, like him, the son of the Sun and of Rhea, was born on the second supplementary day. He is also called the elder Horus, and is considered by some of the Greeks as their Apollo.

12. Typhon, the spurious son of Rhea and Cronus, was born on the third supplementary day, and married his sister Nephthe.[†] He is characterized by a red colour, and is supposed to have been a personification of the effects of scorching heat. He is also compared to the earth's shadow, as causing eclipses of the moon. The celestial habitation of his soul was supposed to be in the Great Bear. According to Plutarch, his Egyptian names were *Seth*, *Bebon* or *Babyn*, and *Smy*; the word Typhon being apparently of Greek origin.

13. Isis, Isi, or Esi, was supposed to be the offspring of Thoth and Rhea, born on the fourth supplementary day; she was also sometimes called the daughter of Prometheus. She is generally compared to Ceres, or the Earth, and is made the deity of fertility and of maternal love. She was also esteemed analogous to Proserpine, as the queen of the lower regions, and the wife of Pluto; thus she is called by Aristides, "the saviour and conductress of souls;" and, in some Roman inscriptions copied by Zoega,[*] she is made "the guardian of the ashes of the dead." Horapollo says, that her head was sometimes adorned with vulture's plumes; but Herodotus tells us, that she was represented with cow's horns, like Io; other authors however say, that, after Horus, in revenge for his father's death, had made Typhon prisoner, Isis imprudently set him at liberty, and Horus, therefore, tore the regal diadem from her brow, but that Thoth or Hermes substituted for it a helmet made of a bullock's head. Her soul was supposed to have its residence in the Dog star, the Sothis of the Egyptians. Her dress was of many colours. She is sometimes compared to the moon; but this idea appears to be foreign to the oldest mythology, as well as to the genius of the Egyptian language. She has also been somewhat arbitrarily confounded with Minerva by Plutarch, in speaking of the inscription of the temple of Saïs, which confessedly related to the Egyptian Minerva, who was indisputably the goddess Neith; although, in consequence of this inattention, the "robe" mentioned in the inscription has been called the "robe of Isis," and the expression has been almost proverbially employed as denoting mystery and secrecy.

14. Nephthe, rather than *Nephthys*, the spurious daughter of Rhea and Cronus, was born on the fifth supplementary day. She is sometimes called by the Greeks *Teleute*, that is, consummation; and sometimes Venus and Victory. She is mentioned by Firmicus as the sister and companion of Isis; and Plutarch says, that the face of Isis was sometimes represented on the sistrum, and sometimes that of Nephthe.

15. Thueris, a concubine of Typhon, is only noticed as having been pursued, on her way to visit Horus, by a huge snake, which was killed by Horus's people.

16. Bebon, who is sometimes confounded with Typhon, is also mentioned as one of his companions.

17. Ares is inserted among the fabulous kings of Manetho. Vettius Valens says, that the planet Mars was called by the Egyptians *Artes*; and Cedrenus makes the name *Ertosi*. Herodotus tells us, that Mars was worshipped at Papremis.

18. Somus, or *Shom*, was probably the personage called the Egyptian Hercules by the Greek writers. Thus, the great Etymologicon has *Chon* for this deity, and Eratosthenes writes his name *Sem*, both of these having been probably intended to express the Coptic jom or sjom, *strength*, which seems sometimes to have been written jem or sjem. Diodorus mentions this Hercules as a general of Osiris, whom he

left behind with Isis. He is said to have been killed by Typhon, but to have been revived by the smell of a quail. Herodotus asserts, that the word Heracles is originally Egyptian; but in this, as in many other instances, his interpreters must have misinformed him, perhaps from misunderstanding his questions; for his Egyptian etymologies are almost uniformly erroneous. Thus, when the priests had shown him, or rather Hecataeus, whose original story he seems to have copied and disfigured, the statues of 341 successive generations of high priests, who were neither gods nor heroes, but each a PIROMIS, the son of PIROMIS; he tells us, that PIROMIS means *beautiful and brave;* while, in fact, the literal sense of PIROMI, in the modern Coptic of Lower Egypt, which is simply *a man*, restores to the observation of the priests an intelligible and consistent sense.

19. BUTO, the nurse of Horus and of Bubastis, compared to the Latona of the Greeks, must be considered as anterior to the birth of Horus.

20. HORUS, *Hor*, *Or*, or *Horsiesi*, was the son of Isis and Osiris. Jablonsky observes, that a King *Ur* is mentioned by Manetho, and that *Or* was, in later times, the name of a certain monk, and *Taor* of a nun: the Egyptians having always, as Lucian informs us, had a propensity to adopt the names of their deities for their own, so that they may have become current in families without any immediate reference to their origin. Akerblad has also found *Horsiesi* as an Egyptian name, and conjectures, not without probability, that it may have meant originally Horus, the son of Isis; SI being an abridgment of SHERI, as it appears also to have been in the name *Siphoas*, or rather *Siphthas*, which is explained by Eratosthenes, *the son of Vulcan*. Horus is often confounded with the Sun, perhaps from the resemblance of his name to the Hebrew AOR, *light;* while Suidas makes him rather analogous to Priapus. He was nursed by Buto, in the city Butus. The most remarkable exploit of his youthful days was the pursuit and conquest of Typhon, in revenge for his father's death. The constellation Orion was supposed to be the habitation of his soul. His dress was white. Damascius, as copied by Photius, informs us that he was represented with his finger on his mouth.

21. HARPOCRATES was a son of Osiris from a visit paid to Isis after his death. He was also born prematurely, and was weak in his lower limbs. Eratosthenes seems to have called him Phrucrates; and PHROKHRAT, in Coptic, would mean dried or *withered feet.*

22. ANUBIS was the offspring of Osiris and Nephthe, whom he had mistaken for Isis, and who exposed the child, but Isis recovered him, and he became her faithful attendant. He was considered as belonging both to the upper and the lower worlds, and was therefore compared to the horizon; and he seems to have been typified by a dog, or figured with a dog's head. He attended Osiris in his military expedition; and he is sometimes erroneously confounded with Mercury, and even with Saturn. A cock was usually sacrificed to him; and Pliny tells us, that his images were properly made of gold, in allusion to his name; a remark which is amply explained by the Coptic word NUB, which still signifies *gold.*

23. ARSAPHES is mentioned by Plutarch as a son of Isis; but the same name is said to have been sometimes applied to Osiris.

24. ATHOR, or *Athyr*, was the Venus of the Egyptians, according to the great Etymologicon. Herodotus mentions a temple of Venus at Atarbechis, which might be translated the city of Venus, BAKI in Coptic meaning city; although Plutarch enumerates Athyri among the different names of Isis. Strabo informs us, that at Momemphis, a sacred cow was fed in honour of Venus.

25. AMUN, the Jupiter of the Egyptians, though apparently a personage of much less importance than the Greek and Roman Jupiter, was worshipped by the Ammonians, under the form of a human figure, with a ram's head. Hecataeus, as quoted by Plutarch, denies that this term is the proper name of the deity, and observes, very truly, that it is an Egyptian word meaning *come*, by which the god was supplicated to appear. The word, however, implies also *glory*, or *splendor*. If there was a more appropriate term for this deity, it may possibly, as Mr Akerblad has observed, have been *Ho*, which was the Egyptian name of the city, called by the Greeks Diospolis the Less. It is remarkable, that Manetho gives us a Zeus distinct from Ammon, interposing Tithoes and Sosus as intermediate kings.

26. ANTAEUS, *Entes*, or *Mendes*, is said to have been left by Osiris as a viceroy or lieutenant governor, together with Busiris, for the assistance of Isis, during his absence. He is generally identified with Pan, though Diodorus mentions Pan as having accompanied Osiris on his expedition. At Mendes a goat was fed in honour of this deity, and Plutarch seems to say, that this goat was called Apis, as well as the bull fed at Memphis. He was also generally represented with the face and legs of a goat. Herodotus calls him one of the eight gods, older than the twelve; but Diodorus makes the eight senior gods of the Egyptians the Sun, Cronus, Rhea, Ammon, Juno, Vulcan, Vesta, and Mercury. Out of these, however, Juno and Vesta cannot easily be identified in the Egyptian mythology.

27. BUSIRIS is only mentioned by Diodorus as a colleague of Antæus in his government.

28. MACEDON, according to Diodorus, was a companion of Osiris in his expedition.

29. BUBASTIS was a sister of Horus, preserved and nursed with him by Buto in the city of Butus. She is compared, by various authors, to Artemis or Diana. Apuleius gives us Bubasthis for the Egyptian name of the plant Artemisia; and Bubastis is addressed in a Greek epigram in the place of Diana, considered in her obstetrical capacity.

30. SARAPIS, an ancient deity of the Greeks, was raised into a more distinguished rank by the honours paid him, as identical with Pluto, by Ptolemy Soter, who had found an image of Pluto at Sinope, accompanied by Cerberus and a dragon, which he brought to Alexandria, and established in the Serapeum there, as belonging to Sarapis. Some of the ancients were, however, of opinion, that the word Sa-

rapis meant only the *feast of Apis*; and, indeed, the Coptic SHAHRI, which signifies to feast, agrees tolerably well with this etymology, however improbable the opinion founded on it may be esteemed. Sarapis is also supposed to have had some relation to the regulation of the Nilometer, which consisted of a column with different heights marked on it, in the centre of a bath or well, into which the water of the river was admitted.

31. ESMUNUS, or *Shmun*, was the eighth son of Sadycus by one of the Titanides, and brother of the Dioscuri and Cabiri; all of them names which seem as foreign to the Egyptian mythology, as the word SHMUN is familiar to the language, meaning simply *eight*. He is, however, said by Damascius to have been the Egyptian Æsculapius, although Manetho gives the name Tosorthrus to this deity, making him a son of Pan and Hephæstobule.

32. PAAMYLES is mentioned by Hesychius and Plutarch as a Priapic deity; he is also made by Cratinus synonymous with *Socharis*.

33. TITHRAMBO, according to Epiphanius, was analogous to the Hecate of the Greeks.

34. THERMUTHIS, though generally understood to be only a name of the sacred serpents worn in the crown of Isis, is distinguished by Epiphanius as an independent deity; and if we may judge by the signification of the Coptic word, which means *mortiferous*, her character must have been somewhat analogous to that of Nemesis.

35. CANOPUS, or *Canobus*, had a temple which is mentioned by Dionysius Periegetes. The jars called Canopi were often made porous, to serve as filters, and are mentioned by Hesychius, in the word *Stactice*, but we are not exactly informed how far they were connected with this deity.

36. MENUTHIS was the wife of Canopus, and seems to have given her name to a village near the town Canopus, which is mentioned by Stephanus. Epiphanius calls her *Eumenuthis*.

37. BESA is only known from Ammianus Marcellinus, who mentions an oracle dependent on him.

38. PROTEUS, though noticed as a king of no very high antiquity, is said to have had a temple erected to him as a hero. Diodorus says that his Egyptian name was Cetes; though Herodotus, as in other instances, fancies, from some misapprehension, that the Greek and Egyptian names were identical; and he observes, that similar honours were also paid to Perseus, another hero known to the Greeks.

39. NILUS, whether as a king, or merely as a river, appears to have received divine honours. The Egyptian name of the Nile seems to have been simply PHIARO, the Ethiopians called it *Siris*; the AMEIRI of Kircher's vocabulary was probably a name of later date.

40. APIS, a bull consecrated to Osiris, was fed, with divine honours, at Memphis, the principal burying place of that deity, of whose soul he was considered as the living image. He was all over black, except some small white spots, and some other particular marks not of common occurrence. He was sometimes said to be the offspring of a cow and a ray of moonlight.

41. MNEUIS, or *Mnyis*, was also a black bull, sacred to Osiris, kept at Heliopolis; although some authors assert that he was sacred to the sun. Ælian mentions also a black bull called Onuphis; and Macrobius, speaks of a bull named Pacis, or Bacis, and kept at Hermonthis. For the cow that was consecrated to Venus, it does not appear that any particular name has been recorded.

SECTION III.—*Historiography of Egypt.*

The early history of Egypt claims a much higher antiquity than that of almost any other nation; and is consequently involved in darkness more impenetrable. It is utterly impossible to reconcile the accounts of various authors with each other; and even the same authors are not always consistent with themselves. But some little idea may be formed of the comparative value of the different catalogues of sovereigns, by observing which of them is confirmed by the testimony of the greatest number of respectable and unconnected writers, and by inquiring, at the same time, what internal evidence they afford of truth or falsehood.

The only original authorities on which we can depend, for the early history of Egypt, are those of Herodotus, Manetho, Eratosthenes, Diodorus Siculus, and Strabo; all of whom had been more or less in the country. Herodotus lived soon after the conquest of Egypt by Cambyses, when the names of the later monarchs could not easily have been forgotten. The earlier part of his history is of a much more apocryphal nature: he does not, however, continue the series of the kings further back than Sesostris and Moeris: so that almost all his names are sufficiently recent to be considered as completely within the province of legitimate history. Manetho lived under Ptolemy Philadelphus, to whom he dedicated his three books of the *History of Egypt*; and there is little doubt that the extracts, preserved by Josephus, Eusebius, and Syncellus, although some of them have passed in succession from one compiler to another, are in general perfectly authentic. How much of the work was originally fabulous, and how much has been distorted by transposition and anachronism, it is impossible accurately to determine: but besides the original inadmissibility of the existence of so long a series of successive generations, the invention of which may possibly have been derived from the same national vanity, that led the priests to boast to Herodotus of 330 kings between Menes and Sesostris, there are several coincidences, which Marsham has pointed out, in the names and qualifications of princes mentioned as having lived at very remote times, tending strongly to encourage the opinion, that the originals of the stories were respectively one and the same person; there are also other instances, in which it is not improbable, that several of the persons enumerated may have been contemporary sovereigns of different subdivisions of the country, although this part of Marsham's theory has perhaps been carried a little too far: and amidst so much confusion, it must be confessed that all his learning and all his ingenuity have been inadequate to the establishment of any satisfactory result. He holds the catalogue of Eratosthenes in high and just estimation, although he was not acquainted with the strong argument in favour of its authenticity, which has been deduced from the agreement of many of the etymologies with the acknowledged meaning of the terms in the Egyptian language; an agreement which makes it more than probable that Eratosthenes, who lived in the reign of Ptolemy Euergetes, did actually receive these names and their interpretations from the priests of Diospolis. This interesting catalogue has been successively copied by Apollodorus, Africanus, Eusebius, and Syncellus; but how many of the names contained in it were really those of actual sovereigns of Egypt, and how many had been negligently or ignorantly read and pronounced, it is by no means easy to ascertain: it can only be observed in general, that scarcely any of them are found in the works of other chronologers or historians. Diodorus is, on the whole, a very candid and judicious writer, and we shall hereafter find some remarkable evidence of his correct knowledge of the Egyptian institutions; although some of the most approved critics of modern times have entertained considerable prejudices against him. The accuracy and good sense of Strabo are so well known, that we can only lament the paucity of the historical facts that can be collected from him. Besides these authors, there is an anonymous chronicle copied by Africanus, and from him by Syncellus, which affords a series of kings somewhat shorter than that of Manetho, and more regularly filled; it seems, however, to be principally a compilation from Manetho, with some regard to the contemporary events of the scriptural chronology.

That Menes, whom many suppose to have been Misraim, the son of Ham, was the first king of Egypt, is fully agreed by all authors; and both Manetho and Eratosthenes make his immediate successor Athothes; and, together with Herodotus, mention Nitocris as one of the early queens. Besides these coincidences, there are slight resemblances in the names of six or seven of the intermediate personages of the respective lists; but it is impossible to pronounce with confidence, that the circumstance is any thing more than accidental: and, in fact, we find little or no collateral confirmation of the accuracy of any others of the appellations, till we come down to the 18th dynasty of Manetho; the Phenician shepherds, who are referred to the 17th, being little mentioned by other historians, and very few, even of their supposed names, having been preserved by Manetho. But we find a particular catalogue of the 18th dynasty both in Josephus and in Eusebius, bringing us down to the time of Sesostris, with whom the histories of Herodotus and Diodorus may be said to begin. So far, therefore, as the chronology of the kings of Egypt can be recovered from these documents, it will stand nearly as in the subjoined table; the dates being deduced from the lengths of the several reigns as given by Manetho alone, taking the means of the different readings of the numbers, and setting out with the presumption, that the conquest of Psammenitus by Cambyses happened 525 years B. C.

According to Manetho.

It is only in the name and order of the nine last sovereigns, that the three catalogues agree so well as to be considered as fully confirming each other: Before these, the Asychis and Anysis of Herodotus are not unlike the Osochon and Psinaches or Sinaches, which stand together at a much earlier period, in the longer list of Manetho. The Cheops, or Chemmis, Chephren, and Mycerinus of the two Greek historians, supposed to be the builders of the pyramids, are no where found in Manetho, who attributes some of these extraordinary edifices to the fourth dynasty, in which we have Suphis, Suphis, and Mencheres, each supposed to have reigned more than sixty years, the names having so much of general resemblance to those of Herodotus, that they may easily have been corruptions of the same originals. It is impossible to conjecture what date we ought to assign to this dynasty, although it is remarkable that the names and characters of several of the kings agree sufficiently well with those of Sesostris and his immediate predecessors, which occur much later in the catalogue. But, considering that not a single hieroglyphical representation has yet been discovered about the pyramids, there is no reason to induce us to bring down their date so low as to this period, much less to believe, with Herodotus, that they were built only twelve generations before the time of Cambyses. The third pyramid, in Africanus's extract from Manetho, is attributed to Nitocris, who is referred to the sixth dynasty. The different passages of Manetho, which Syncellus has copied from Africanus and from Eusebius, exhibit many other variations, both in names and dates, which would require the catalogue to be considerably extended, if we admitted into it all the personages enumerated; while, on the other hand, a comparison with other authorities makes it more desirable that we should abridge the whole period by about 300 years out of the 1350 which it occupies, in order that Thuthmosis or Amosis might become contemporary with Moses, as Josephus makes him. But it is obvious that this degree of anachronism is not enough to vitiate the general truth of Manetho's statement of the names and order of succession of the sixty or seventy sovereigns preceding Cambyses; at the same time we must admit the accuracy of the respective dates with considerable latitude, and the more as their antiquity becomes greater. Thus the taking of Troy is mentioned as having happened in the time of Thuoris, the commencement of whose reign our catalogue makes 1233 B. C., that is, only 50 years earlier than the date assigned to this event from other authorities; and Petubastes, who is said to have been reigning at the institution of the Olympiads, stands full 50 years too far back for the commencement of the Olympic era, though he is somewhat more modern than the date at which Iphitus is said to have instituted the games. It would, however, be unreasonable to expect, considering the imperfect nature of the evidence that we possess, a coincidence much more accurate.

SECTION IV.—*Of the Egyptian Calendar.*

From the chronology of Egypt, we may pass very naturally to the consideration of its calendar, which has often been a subject of speculation both with critics and with astronomers. The inquiry is in itself somewhat intricate; but the principal difficulties have arisen from the ignorance or carelessness of the Greek authors, who have written on the Egyptian mythology. The Baron Alexander von Humboldt and Mr Jomard have displayed great learning and research in collecting authorities on this subject; and nothing is wanting, to establish the propriety of their acquiescence in the opinion of Petavius, except a little less indulgence for the extreme inattention of Plutarch, and a more marked deference to the important testimony of Eratosthenes, a writer whose catalogue of the Egyptian kings has already been noticed, as bearing intrinsic marks of the authenticity of his information, and whose competency, as an accomplished astronomer, to discuss the regulation of the calendar, is of still greater notoriety. Geminus, a Greek astronomer of the Augustan age, has very distinctly stated, that the later Greeks had been in the habit of mentioning the Egyptian festivals as connected with particular seasons of the year, in spite of the clearest evidence that their mythological year consisted of 365 days only, and that their anniversary festivals must necessarily have passed in succession through every part of the natural year. "It is a common and inveterate error among the Greeks," says Geminus, "to believe that the festival of Isis happens at the winter solstice. This was indeed true 120 years ago; but it is now a month earlier; and such a mistake betrays the grossest ignorance of the Egyptian calendar. In former ages, this festival was celebrated not only as late as the winter solstice, but, at an earlier period of time, even at the summer solstice; as Eratosthenes expressly states, in his *Commentary upon the Octaeterides.*" (*Geminus in Petav. Uranologia.* Par. 1630, f. p. 33.)

The later inhabitants of lower Egypt, and especially the Greeks of Alexandria, had certainly a stationary as well as a wandering year; but this was no other than the Julian year, which was introduced here some little time after its establishment in other parts of the Roman empire; and which was probably the only year ever employed by the Coptic Christians, although it can scarcely have been adopted at any time by the Pagan Egyptians. The common opinion is, that the Julian calendar was established at Alexandria, in the year 25 B. C., the first month Thoth then beginning on the 29th of August, as the Coptic year continued to do ever after. Thus Vansleb found, in the seventeenth century, that Thoth began on the 8th of September N. S., which was the 29th of August O. S. A passage of Theon, in his *Commentary on Ptolemy*, would rather incline us to fix on the 1st September for the beginning of the Alexandrian year; but the ecclesiastical authority is more direct, and it is confirmed by the present usage of the Abyssinian church. The quadriennial intercalation of a sixth supplementary day took place, according to the Abbé Boyer, at the end of the second year after the Julian bissextile; so that, in the year preceding the bissextile, the first of Thoth happened on the 30th of August. From these authorities, we have no difficulty in ascertaining the beginning of the ancient or moveable Egyptian year for any earlier or later period; reckoning both ways, for the sake of simplicity, in Julian years.

B. C. 1500	2d Sept. O. S.	B. C. 400	1st Dec.
1400	8th Aug.	300	6th Nov.
1300	14th July.	200	12th Oct.
1200	19th June.	100	17th Sept.
1100	25th May.	B. of C.	23d Aug.
1000	30th April.	100	29th July.
900	5th April.	200	4th July.
800	11th March.	300	9th June.
700	16th Feb.	400	15th May.
600	21st Jan.	500	20th April.
500	26th Dec.		

It is of importance, in the discussion of some representations of astronomical objects, to determine at what time of the year the sun entered the respective signs, according to the Egyptian calendar, or, more particularly, what was the sun's place in the starry zodiac at the commencement of the year, for different periods of time. Taking, then, 6 h. 9′ 8″ for the excess of the sidereal above the Egyptian year, we find that 1424 Julian years were required for a complete revolution of the sun's place on the 1 Thoth, and 119 for each sign. Now since, about a century before the establishment of the Julian calendar, the sun entered Libra on the 24th of September; and since the Egyptian year began on that day, in 120 B. C., it follows that Libra had been the first constellation during the whole of the preceding century; for, at this period, the beginning and end of the signs of the ecliptic agreed very nearly with those of the corresponding constellations of the zodiac. The first constellation of the Egyptian year will therefore stand nearly thus:

From 1552 B. C.		484	♑
to 1433	♍	365	♐
1314	♌	247	♏
1196	♋	128	♎
1077	♊	9	♍
958	♉	A. C. 110	♌
840	♈	228	♋
722	♓	347	♊
603	♒		

We may take, for an example of an Egyptian date, that of the Rosetta stone, in the ninth year of Ptolemy Epiphanes, or 196 B. C., when the Egyptian year must have begun on the 11th of October; consequently, the first of the sixth month, Mechir, was the 9th of March, and the 18th of Mechir, which is made synonymous with the 4th of Xanthicus, the 26th of March: so that Xanthicus must constantly have begun on the 22d of March, if the intercalations were properly adjusted; and this agrees sufficiently well with Usher's table of the Macedonian "lunar" months, which may therefore be supposed to have been generally employed by the Greeks in Egypt.

If we attempt to determine the date of a given monument from astronomical symbols contained in it, we must suppose that they represented the state of the heavens with respect to the Egyptian year at the time in question. Thus, in the zodiacs of the ruins at and near Esne or Latopolis, the constellation Pisces seems to be the first sign, as it really was, about 800 B. C. or in the time of Bocchoris and of the Ethiopian dynasty. It is, however, equally possible, that Virgo may have been intended for the first sign, and this would answer either to the century immediately preceding the birth of Christ, or to a period fourteen centuries earlier. The zodiac at Dendera appears to begin with Leo; and unless we suppose its antiquity extravagantly great, we must refer it to the time of Tiberius, as Visconti has indeed already remarked. Mr Hamilton has confirmed this opinion by the collateral evidence of inscriptions in honour of the Roman emperors: although, with respect to the difference of time implied by the difference of a sign in the beginning of the zodiacs, he is rather inclined to adopt the sentiments of Lalande, who refers it to the effect of the precession of the equinoxes; imagining, without any kind of authority, that the division of the signs corresponded to the period of the solstices, a period which never constituted a marked feature in the Egyptian calendar.

Calendar.

In the zodiac at Esne, the sign Libra is denoted, as is usual in the Roman representations, by a female holding the balance; while the Egyptian constellation, in most other instances, is without the female. Servius, however, informs us, that the Romans borrowed this sign from the Egyptians, the Greek astronomers having considered it as a part of the Scorpion; so that there is no reason to question the antiquity of the ceiling, from the occurrence of this constellation in it. The sign Cancer, both here and elsewhere, has eight feet, and it has certainly no connexion with the figure of the sacred beetle, which occurs many thousands of times in other places, but never with more than six feet.

The beetles in the zodiac of Dendera have a very different signification, and the whole representation is much more of a mythological than of an astronomical nature. The beetle near the beginning of the zodiac is the well known symbol of generation, and he is in the act of depositing his globe: on the opposite side, at the end of the zodiac, is the head of Isis, with her name, as newly born; both the long female figures are appropriate representations of the mother; and the zodiac between them expresses the "revolving year" which elapsed between the two periods. This explanation is completely confirmed by a similar representation of two female figures on the ceiling of the first tomb of the kings at Byban El Molouk; one with the beetle, the other with the name of the personage just born: between them, instead of the zodiac, are two tablets, divided into 270 squares, or rectangles, corresponding to the number of days in nine Egyptian months, with ten circles placed at equal distances, probably intended to represent full moons, and relating to the ten incomplete lunations to which these days must belong. The number 270 is too remarkable to be supposed to have been introduced by mere accident; and when the argument is considered as a confirmation of other evidence, in itself sufficiently convincing, the whole must be allowed to be fully conclusive.

There is indeed little chance of our discovering any astronomical records of importance among the profusion of hieroglyphical literature which is still in existence. Horodotus tells us, that the Greeks derived their acquaintance with astronomy from the Babylonians, though they were supposed to have learned the elements of geometry from the Egyptians; and it is well known that Ptolemy the astronomer, who lived at Alexandria, and who must have had easy access, as well as Eratosthenes before him, to all the knowledge of the Egyptian priests, refers to no Egyptian observations, but employs the Babylonian records of eclipses which had happened a few centuries before his time; records, which, as Pliny informs us, were preserved on a particular kind of bricks, the same, perhaps, that have been brought to Europe in our own times, as undeciphered specimens of the nail, or arrow headed character. But a certain degree of geometrical knowledge can scarcely be denied to a people, who had made very considerable progress in sculpture and architecture, at a time when all Europe was immersed in the profoundest barbarism, and who must necessarily have had frequent occasion for the employment of agrarian measurements. The Egyptians must also have been good practical chemists; so far, at least, as was required for the preparation of brilliant and diversified and durable pigments: and even their devotion to alchemy, which derives its name from having been the *secret* or *dark* study of Egypt, must have led them to make some little progress in experimental philosophy, although neither their manufacturers nor their magicians could have any right to boast of solid acquirements in genuine science.

Customs and Ceremonies.

The months of the fixed or Alexandrian year were these:

1.	Thoth,	began 29th August, O. S.
2.	Paopi,	28th September.
3.	Athor,	28th October.
4.	Chocak,	27th November.
5.	Tobi,	27th December.
6.	Mechir,	26th January.
7.	Phamenoth,	25th February.
8.	Pharmuthi,	27th March.
9.	Pashons,	26th April.
10.	Paoni,	26th May.
11.	Epep,	25th June.
12.	Mesore,	25th July.

The years are commonly dated from the era of the martyrs of Diocletian, beginning in the autumn of 284.

SECTION V.—*Egyptian Customs and Ceremonies.*

Herodotus, Diodorus Siculus, and Plutarch, have entered at large into an account of the manners and opinions of the ancient Egyptians; but it is difficult to ascertain in what precise proportion we ought to consider their information as accurate. A few insulated observations are, however, sufficiently striking to attract our attention; and there are some passages of Strabo, whose veracity, with respect to what he had seen, is undoubted, that will serve to afford us an introductory view of some of their usages. He gives us, for example, an interesting description of the usual form of the Egyptian temples, and of the habits of the sacred animals, which were frequently kept in them. "At the entrance of the sacred inclosure," he says (Book 17), "there is a paved area, about a hundred feet wide, or a little less, and three or four times as long, or sometimes even more: this area is called the dromus, or course, as in the line of Callimachus, 'This sacred course the great Anubis claims.' On each side of the whole length of this area is a row of sphinxes of stone, at the distance of 30 feet, or a little more, from each other; one row on the right hand, and the other on the left. Beyond these is the first great propylon; then, as you advance, a second and a third; their number not being limited, any more than that of the sphinxes, but both varying in various temples, as well as the length and breadth of the dromus. Next to the propyla is the temple, properly so called, consisting of a large and splendid pronaos, and a moderate cella or secos, without any image, at least in a human form, but commonly with the representation of some animal. On each side of the pronaos

Customs and Ceremonies.

there is a projecting wing; that is, a wall of equal height with the temple; at the beginning of the wings, their distance from each other is a little more than the breadth of the extreme border of the temple, but as we advance forwards, they incline till it becomes about 80 or 90 feet. The walls are sculptured with the representations of large figures, in the style of the Etruscan, or the very ancient Greek decorations. Some of their buildings are encumbered with a multitude of columns, as at Memphis, in a barbarous style of architecture; for, besides that the columns are heavy, and numerous, and in a variety of rows, they have nothing graceful nor picturesque about them, but merely exhibit ill directed labour, without good taste.

"At Heliopolis we saw some large buildings appropriated to the accommodation of the priests; and it is said that this colony or college was formerly remarkable for the residence of philosophers and astronomers; but their habits and studies are no longer of so refined a nature. It was here that Plato and Eudoxus passed a considerable time; and, as some say, not less than thirteen years; for the priests were very cautious of imparting their knowledge; and though courted patiently by all sorts of attentions, would at last only communicate to them a small part of the theorems which they had discovered. They taught them, however, the true length of the year, as exceeding 365 days; but the Greeks were not accurately acquainted with its magnitude, until they had obtained translations of the sacred commentaries of the Egyptians.

"At Memphis, the capital of Egypt, there are several temples, among which is that of Apis, or Osiris, where the bull Apis is fed, in a sacred stable, being honoured as a deity: he has white spots on his forehead, and on some other small parts of his body, but with this exception he is completely black. In front of the stable is a court, with another stable appropriated to his mother: into this court the bull is turned at certain hours, especially when he is to be exhibited to strangers, who, however, are allowed to see him at other times through a window of his stable: when he has leaped about and taken his exercise, he is soon shut up again. In the dromus of the temple of Vulcan it is usual to exhibit combats of bulls, the animals being fed for this express purpose. There is also a temple of Aphrodite or Venus, and another of Serapis in a very sandy place, where we saw some of the sphinxes already buried up to the necks by the effect of the winds."—"In the city of Arsinoe, which was formerly called Crocodilopolis, the crocodile is worshipped, and a sacred crocodile is kept in a pond, who is perfectly tame, and familiar with the priests. He is called Suchus; they feed him with corn, and meat, and wine, which are continually brought him by strangers. The friend who conducted us had provided a cake, and some meat, and a vessel of water and honey: we found him on the bank of his pond; the priests held open his mouth, while one of their number put the cake and the meat into it, and then poured the liquor on them; the animal then jumped into the pond, and crossed to the opposite side, where he was again fed in a similar manner, with the offerings of another visitor." It appears, therefore, that in the days of Augustus these sacred animals were not regarded with much more awe than the inmates of a menagerie in modern times.

The stories of Herodotus, though told with an elegant simplicity, and with every appearance of good faith, are by no means free from a frequent mixture of fable; and, with respect to his Egyptian etymologies, he is almost universally mistaken; but his account of the ceremonies observed in the preparation of the mummies has many marks of authenticity, and he is perfectly correct in asserting that the most splendid of the coffins are formed in imitation of the figures of Osiris; a circumstance which he could not easily have conjectured without direct and accurate information.

There is, however, a still stronger confirmation of the veracity of Diodorus Siculus, from the coincidence of a number which he mentions, with a variety of Egyptian monuments still existing. He tells us that a talent of silver was sometimes expended on the funeral of an individual. "The relations of the deceased announce," he says, "to the judges, and to all the connexions of the family, the time appointed for the ceremony, which includes the passage of the deceased over the lake or canal of the nome to which he belonged. *Two and forty* judges are then collected, and arranged in a semicircle, which is situated beyond the canal; the boat is prepared, and the pilot is called by the Egyptians Charon; whence it is said that Orpheus borrowed the mythological character of this personage. Before the coffin is put into the boat, the law permits any one that chooses to produce his accusations; and if it is proved that the life of the deceased was criminal, the funeral is prohibited, while all false accusations are severely punished. If there are no accusations, or when they have been repelled, the relations of the deceased lay aside their lamentations, and pronounce his encomiums; asserting that he is about to pass a happy eternity with the pious, in the regions of Hades; and the body is finally deposited in the catacomb prepared for it." The history of so extraordinary a ceremony certainly required some confirmation to make it appear consistent with probability; but the number of forty two judges is found in a great variety of pictural representations, and in some inscriptions, so that the account must have been given by a person well acquainted with the practice of the country; and, when thus established, it demonstrates also the truth of the received opinion, that the Egyptians believed in a future state of rewards and punishments. (*Phil. Trans.* 1819.)

In cases of civil law suits, the number of judges, according to the same author, was only thirty; their president wearing a breast-plate adorned with jewels, which was called Truth. The eight books of the laws were placed near the judges: the pleadings of the advocates were all conducted in writing only, in order that the feelings of the judges might not be improperly biassed by the too energetic eloquence of an impassioned orator; and the president delivered the sentence of his colleagues, by the form of touching the successful party with the symbol of justice which he wore.

SECTION VI.—*Analysis of the triple inscription of Rosetta.*

Having acquired some preliminary notions of the mythology and history, and chronology and institutions, of ancient Egypt, we may proceed to the discussion of its written language and literature, as far as they are likely to be recovered from existing monuments; and, first of all, we must inquire into the best mode of obtaining some satisfactory conclusions from the invaluable inscriptions in honour of Ptolemy Epiphanes; which contain the only authentic specimen in existence of hieroglyphical characters, expressly accompanied by a translation.

The block or pillar of black basalt, found by the French in digging up some ground at Rosetta, and now placed in the British Museum, exhibits the remains of three distinct inscriptions; and the last, which is in Greek, ends with the information, that the decree, which it contains, was ordered to be engraved in three different characters, the sacred letters, the letters of the country, and the Greek. Unfortunately a considerable part of the first inscription is wanting: the beginning of the second, and the end of the third, are also mutilated; so that we have no precise points of coincidence from which we can set out, in our attempts to decipher the unknown characters. The second inscription, which it will be safest to distinguish by the Greek name *enchorial*, signifying merely the characters " of the country," notwithstanding its deficiencies near the beginning, is still sufficiently perfect to allow us to compare its different parts with each other, and with the Greek, by the same method that we should employ if it were entire. Thus, if we examine the parts corresponding, in their relative situation, to two passages of the Greek inscription in which *Alexander* and *Alexandria* occur, we soon recognise two well marked groups of characters resembling each other, which we may therefore consider as representing these names; a remark which was first made by Mr de Sacy, in his Letter relating to this inscription. A small group of characters, occurring very often in almost every line, might be either some termination, or some very common particle: it must, therefore, be reserved till it is found in some decisive situation, after some other words have been identified, and it will then easily be shown to mean *and.* The next remarkable collection of characters is repeated twenty nine or thirty times in the enchorial inscription; and we find nothing that occurs so often in the Greek, except the word *king,* with its compounds, which is found about thirty seven times. A fourth assemblage of characters is found fourteen times in the enchorial inscription, agreeing sufficiently well in frequency with the name of *Ptolemy,* which occurs eleven times in the Greek, and generally in passages corresponding to those of the enchorial text in their relative situation; and, by a similar comparison, the name of Egypt is identified, although it occurs much more frequently in the enchorial inscription than in the Greek, which often substitutes for it country only, or omits it entirely. Having thus obtained a sufficient number of common points of subdivision, we may next proceed to write the Greek text over the enchorial, in such a manner that the passages ascertained may all coincide as nearly as possible; and it is obvious that the intermediate parts of each inscription will then stand very near to the corresponding passages of the other.

In this process, it will be necessary to observe that the lines of the enchorial inscription are written from right to left, as, Herodotus tells us, was the custom of the Egyptians; the division of several words and phrases, plainly indicating the direction in which they are to be read. It is well known that the distinct hieroglyphical inscriptions, engraved on different monuments, differ in the direction of the corresponding characters: they always face the right or the left of the spectator according as the principal personages of the tablets, to which they belong, are looking in the one or the other direction; where, however, there are no tablets, they almost always look towards the right; and it is easily demonstrable that they must always have been read beginning from the front, and proceeding to the rear of each rank. But the Egyptians seem never to have written alternately backwards and forwards, as the most ancient Greeks occasionally did. In both cases, however, the whole of the characters thus employed were completely reversed in the two different modes of using them, as if they were seen in a glass, or printed off like the impression of a seal.

By pursuing the comparison of the inscriptions, thus arranged, we ultimately discover the signification of the greater part of the individual enchorial words; and the result of the investigation leads us to observe some slight differences in the form and order of some parts of the different inscriptions, which are indicated in the " conjectural translation," published in the *Archæologia* and in the *Museum Criticum.* The degree of evidence in favour of the supposed signification of each assemblage of characters may be most conveniently appreciated, by arranging them in a lexicographical form, according to the words of the translation; the enchorial words themselves not readily admitting a similar arrangement: but the subject is not of sufficient interest for the public, to make it necessary that this little lexicon should be engraved at length.

It might naturally have been expected that the final characters of the enchorial inscription, of which the sense is thus determined with tolerable certainty, although the corresponding part of the Greek is wanting, would have immediately led us to a knowledge of the concluding phrase of the distinct hieroglyphical characters, which remains unimpaired; [illegible] the agreement between the two conclusions is by no means precise; and the difficulty can only be removed by supposing the king to be expressly named in the one, while he is only designated by his titles in the other. With this slight variation, and with the knowledge of the singular accident, that the name of Ptolemy occurs three times in a passage of the enchorial inscription, where the Greek has it but twice, we proceed to identify this name among the sacred characters, in a form sufficiently conspicuous, to have been recognised upon the most superficial examination of the inscriptions, if this total disagreement of the frequency of occurrence had not imposed the condition of a long and laborious investigation, as an indispensable requisite for the solution of so much of the enigma: this step, however, being made good, we obtain from it a tolerably correct scale for the comparative extent of the sacred characters, of which it now appears that almost half of the lines are entirely wanting, those which remain being also much mutilated. Such a scale may also be obtained, in a different manner, by marking, on a straight ruler, the places in which the most characteristic words, such as *god*, *king*, *priest*, and *shrine* occur, in the latter parts of the other inscriptions, at distances proportional to the actual distances from the end; and then trying to find corresponding characters among the hieroglyphics of the first inscription, by varying the obliquity of the ruler, so as to correspond to all possible lengths which that inscription can be supposed to have occupied, allowing always a certain latitude for the variations of the comparative lengths of the different phrases and expressions. By these steps it is not very difficult to assure ourselves, that a *shrine* and a *priest* are denoted by representations which must have been intended for pictures of objects denoted by them; and this appears to be the precise point of the investigation at which it becomes completely demonstrative, and promises a substantial foundation for further inferences. The other terms, *god* and *king*, are still more easily ascertained, from their situation near the name of Ptolemy.

The most material points of the three inscriptions having been thus identified, they may all be written side by side, and the sense of the respective characters may be still further investigated, by a minute comparison of the different parts with each other. The last line of the sacred characters, with the corresponding parts of the other inscriptions, will serve as a fair specimen of the result that has been attained from these operations. (Plate LXXVIII. M.)

In thus comparing the enchorial with the sacred characters, we find many coincidences in their forms, by far too accurate to be compatible with the supposition that the enchorial could be of a nature purely alphabetical. It is evident, for example, that the enchorial characters for a *diadem*, an *asp*, and *everliving*, are immediately borrowed from the sacred. But this coincidence can certainly not be traced throughout the inscriptions; and it seemed natural to suppose, that alphabetical characters might be interspersed with hieroglyphics, in the same way that the astronomers and chemists of modern times have often employed arbitrary marks, as compendious expressions of the objects which were most frequently to be mentioned in their respective sciences. But no effort, however determined and persevering, had been able to discover any alphabet, which could fairly be said to render the inscription, in general, at all like what was required to make its language intelligible Egyptian; although most of the proper names seemed to exhibit a tolerable agreement with the forms of letters indicated by Mr Akerblad; a coincidence, indeed, which might be found in the Chinese, or in any other character not alphabetical, if they employed words of the simplest sounds for writing compound proper names.

The question, however, respecting the nature of the enchorial character, appears to be satisfactorily decided by a comparison of various manuscripts or papyrus, still extant, with each other. Several of these, published in the great *Déscription de l'Egypte*, have always been considered as specimens of the alphabetical writing of the Egyptians, and certainly have as little appearance of being imitations of visible objects, as any of the characters of this inscription, or as the old Arabic or Syriac characters, to which they bear, at first sight, a considerable resemblance. But they are generally accompanied by tablets, or delineations of certain scenes, consisting of a few visible objects, either detached, or placed in certain intelligible relations to each other; and we may generally discover traces of some of these objects, among the characters of the text that accompanies them. A similar correspondence between the text and the tablets is still more readily observed in other manuscripts, written in distinct hieroglyphics, slightly, yet not inelegantly traced, in a hand which appears to have been denoted by the term *hieratic*; and by comparing with each other such parts of the text of these manuscripts, as stand under tablets of the same kind, we discover, upon a very minute examination, that every character of the distinct hieroglyphics has its corresponding trace in the running hand; sometimes a mere dash or line, but often perfectly distinguishable, as a coarse copy of the original delineation, and always alike when it answers to the same character. The particular passages which establish this identity, extending to a series of above ten thousand characters, have been enumerated in the *Museum Criticum;* they have been copied in adjoining lines, and carefully collated with each other; and their number has been increased, by a comparison with some yet unpublished rolls of papyrus, lately brought from Egypt. A few specimens from different manuscripts will be sufficient to show the forms through which the original representation has passed, in its degradation from the *sacred* character, through the *hieratic*, into the *epistolographic*, or common running hand of the country. (Plate LXXVIII. N.)

It seems at first sight incomprehensible, that this coincidence, or rather correspondence, should not be equally observable in the two inscriptions of the Rosetta stone, which, if the enchorial character is merely a degradation of the sacred, must naturally be supposed to be as much alike as those of the different manuscripts in question; while, in reality, we can but seldom trace any very striking analogy between them. But the enchorial character, having been long used in rapid writing, and for the ordinary purposes of life, appears to have become so indistinct in its forms, that it was often necessary to add to it some epithet or synonym, serving to mark the object more distinctly: just as, in speaking Chinese, when the words are translated from written characters into a more limited number of sounds, it is often necessary, on account of the imperfection of the oral language, to add a generic word, in order to determine the signification, and to read, for example, *a*

Triple Inscription of Rosetta.

goose bird, when *a goose* only is written, in order to distinguish it from some other idea implied by a similar sound; and even in English we might sometimes be obliged to say *a yew tree*, in order to distinguish it from *a ewe sheep*, or *you yourself*, or *the letter u*. The enchorial character, therefore, though drawn from the same source, can scarcely, in this form, be called the same language with the sacred hieroglyphics, which had probably remained unaltered from the earliest ages, while the running hand admitted all the variations of the popular dialects, and bore but a faint resemblance to its original prototype. Indeed, if it had been completely identical, there could have been no propriety in repeating the inscription with so slight a change of form.

The rituals and hymns, contained in the manuscripts which have been mentioned, are probably either of higher antiquity than the inscription of Rosetta, or had preserved a greater purity of character, as having been continually copied from older originals. It is also remarkable, that, in one of these rolls of papyrus, engraved by Denon, the introduction is in the sacred character, and some of the phrases contained in it may be observed to be repeated in the subsequent part of the manuscript, which is in a kind of running hand, though somewhat less degraded than in most other instances.

It was not unnatural to hope, that the comparison of these different manuscripts would have assisted us very materially in tracing back all the enchorial characters to the corresponding hieroglyphics, as far as the parts of the respective inscriptions remain entire, and even in filling up the deficiencies of the sacred characters, where they are wanting; and something has certainly been gained from it with respect to the names of several of the deities; but on account of the differences which had crept in between the forms of the language, expressed by the sacred and the cursive characters, the advantage has hitherto been extremely limited. It seems, indeed, to have been a condition inseparable from the whole of this investigation, that its steps should be intricate and laborious, beyond all that could have been imagined from our previous knowledge of the subject; and that, while a number of speculative reasoners have persuaded themselves, at different times, that they were able to read through a hieroglyphical inscription in the most satisfactory manner, beginning at either end, as it might happen, the only monument that has afforded us any real foundations for reasoning on the subject, is more calculated to repress than to encourage our hopes of ever becoming complete masters of the ancient literature of Egypt; although it is unquestionably capable of serving as a key to much important information, with respect to its history and mythology; nor is it by any means impossible, that a careful consideration of other monuments already known, or of such as are now discovered from day to day, may enable us to detect a number of unknown characters, so situated with respect to others, which are already understood, as to carry with them their own interpretation, supported by a degree of evidence far exceeding mere conjecture. We are now to proceed to an enumeration of the principal characters, which have already been rendered intelligible.

Hieroglyphic Vocabulary.

SECTION VII. *Rudiments of a Hieroglyphical Vocabulary.*

A. DEITIES. (PLATE LXXIV.)

1, 2. The word GOD is always represented in the inscription of Rosetta, and often in many others, by a character resembling a particular kind of hatchet, which is delineated repeatedly at Medinet Abou, as a weapon in the hands of warriors, and is even found among the modern weapons engraved by Denon, (*Plate XCV.*) This character is frequently exchanged, in parallel passages of different manuscripts, or of the same, for a figure sitting or standing without distinct arms or feet, either with a human head or a hawk's head; or sometimes, by a deviation from the correct nature of an abstract or general term, with the heads of different animals, according to the character of the deity to whom it is applied. But in the inscription of Rosetta, this symbol appears to be exclusively appropriated to the gods in their JUDICIAL capacity; and it occurs several times in the term meaning *lawful*, n. 151. This interpretation is also fully justified by the testimony of Plutarch, that "the figures of *judges* were represented without hands."

3. A GODDESS is denoted by the hatchet or sitting figure, with the addition of the female characteristic, generally as a termination; but sometimes the simple character is applied to gods and goddesses indifferently. The semicircle and oblique oval, distinguishing the feminine gender, are observable in almost all well marked names of females found in different tablets, and the crooked line, which corresponds to them, in the enchorial character of the stone of Rosetta, may be distinguished at the end of each of the five names of females that occur in the inscription, n. 58, 60, 69, 70, 71. Occasionally the characteristic is prefixed, and this position agrees better with the Coptic TI, which distinguishes a female: nor must we omit to observe, that a semicircle seems to answer to the T in some other cases, and is always expressed in the running hand by the character which Mr Akerblad calls T or D, and which is also exactly the Syriac T. The asp or basilisc standing erect is a symbol of divinity, which occurs on the green sarcophagus, called the tomb of Alexander, and elsewhere, instead of the more ordinary character. In a few instances, the semicircle is found without the oblique oval, (n. 57.)

4. The plural, GODS, is formed by repeating the character three times, or by placing three dashes after, or sometimes before it. In the enchorial inscription, the dashes are united into a crooked line, and are placed in this instance both before and after the principal character; but, in general, the second line is straighter than the first. The dual is expressed by a double character only, (n. 57.)

5. A winged globe, sometimes flattened, as if intended for an egg, but often coloured red, is very commonly represented as hovering over a hero, and generally occupies the lintel of some of the doors of a temple. A globe nearly similar is also sometimes connected with the head and tail of a serpent, bearing the symbol of *life*, which is the common charac-

teristic of a deity. There can, therefore, be no objection to considering these representations as belonging to the *Agathodæmon*, or *Chnuphis* of the Greek authors; and the same symbol is sometimes found in the text of an inscription, in the neighbourhood of the pictural representation; so that its sense may be considered as tolerably well ascertained; but the evidence being somewhat indirect, the name is inserted in smaller characters, the same distinction being also observed in other instances. Mr Bruce informs us, in his letter to Wood, that in some parts of the Tunisian dominions, serpents are still regarded as a kind of good angels. The Chnubis, or Chnumis, of the amulets, is generally represented as a serpent with a human head, or with that of a lion; and the former combination is not uncommon in the tablets of the manuscripts; but the hieroglyphic denoting it is a long undulated line, totally distinct from this character.

6. The symbol, often called the *Hieralpha*, or sacred A, corresponds, in the inscription of Rosetta, to PHTHAH, or Vulcan, one of the principal deities of the Egyptians; a multitude of other sculptures sufficiently prove, that the object intended to be delineated was a plough or hoe; and we are informed by Eusebius, from Plato, that the Egyptian Vulcan was considered as the inventor of instruments of war and of husbandry. In many other inscriptions, the pedestal or pulley is used indifferently for the plough. Horapollo tells us, that Vulcan was denoted by a beetle; and the Monticœlion obelisc of Kircher has the plough on three sides, and the beetle on the fourth: Horapollo, however, is seldom perfectly correct; and the names of different divinities are frequently exchanged on the banners of the same obelisc; nor is there any clear instance of such an exchange of the plough for the beetle as occurs perpetually in the case of the pedestal. The beetle is frequently used for the name of a deity whose head either bears a beetle, or is itself in the form of a beetle; and in other instances the beetle has clearly a reference to generation or reproduction, which is a sense attributed to this symbol by all antiquity; so that it may possibly sometimes been used as a synonym for Phthah, as the father of the gods. The plough is very rarely found as the name of a personage actually represented, and it is difficult to say under what form the Egyptian Vulcan was chiefly worshipped; but on the tablet of a Horus of bad workmanship, belonging to the Borgian Museum, he is exhibited with a hawk's head, holding a spear; while in the great ritual of the *Déscription de l'Egypte*, Ant. II. [illegible] 72. Col. 104, he seems to be represented by a figure with a human head; an exchange, however, which is very common in some other cases, with respect to these two personifications, though it does not extend to the substitution of the heads of different animals for each other.

7. AMMON, the Egyptian Jupiter, is sufficiently identified by a combination of evidence of various kinds, although no single link of the chain extends very far. A figure with a ram's head is denoted, both on the green sarcophagus, and on the temple at Elephantine, by a water jar, sometimes, but not always, accompanied by a bird: now a water jar of this form is constantly converted, in the running hand of the manuscripts, into a character like a Z; and this character, in the enchorial text of Rosetta, is made to express the name of Jupiter; a fact which confirms the testimony of the Greek authors, who consider the Egyptian Jupiter as having been represented with a ram's head. A similar figure is found at Edfou, or Apollinopolis Magna, and at Esne or Latopolis: the temple at Edfou seems to have been dedicated by Amenophis or Memnon; and he appears to be called *lover of Ammon*, that is MIAMUN, which is not unlike the name MEMNON.

8. The common astronomical diagram for the sun, ☉, seems to have been adopted by the Latin astrologers from their masters in Egypt; since it is not very probable that both should have employed a point in the centre of the circle, without some communication with each other; the circle alone having been mentioned by some of the Greek authors, who say, that it was the symbol of the sun. The deity RE or PHRE is indicated by this character followed by an upright bar; and the circle is often enveloped in the coil of the body of a serpent; an oval and an arm also often follow the circle. The enchorial name of the sun is extremely like that which corresponds in the manuscripts to this hieroglyphic: and a similar circle, with rays diverging from it, though seldom exactly in straight lines (N. 160), is used in the sense of "enlightening," or "rendering illustrious:" and it has also been observed by some of the French, who have been in Egypt, to stand in several inscriptions with a manifest reference to light. The circle occurs also as a part of the terms month and day (N. 178, 179). In the great Hieratic Ritual, and in some other manuscripts, this name of Phre occurs very frequently under or near the tablet which contains a representation of the sun shining, as well as under the next to it, which exhibits a head rising out of a lotus, an emblem, mentioned by Plutarch as relating to the sun, which here is made to spring from the pedestal (N. 6), as the sun is said to have been the offspring of Phthah. Whatever plant this lotus may have been, it certainly does not much resemble the nelumbo of the east, which some imagine to have been the original emblem of fertility. The name Phre is almost the only intelligible combination of letters that ever occurs on the Abraxas or amulets; and the monster, to which it relates, has generally radiations from its head, and is surrounded by six stars. The tablets of the sun in the manuscripts exhibit also little genii worshipping him, each of which is always marked "*star god.*"

9. The name of RHEA may, without impropriety, be assigned to a female personage very commonly accompanying the sun, and distinguished by many of his attributes; although the evidence would have been somewhat more conclusive, if the name had been found attached to the figure of the mother in the tablet of the birth of Isis. On the coffins of the mummies, this personage is generally represented with outstretched wings: in other tablets without wings: but she carries in both cases a circle on her head, emblematic of the sun. If we considered the analogy of the hieroglyphic name only,

we should be disposed to interpret it as meaning the wife or sister of Ammon.

10. Ioh, the Moon, is not a deity of very frequent occurrence; but the character is easily interpreted, both from its form, and from its being found, in a different position, as a part of the word month. (N. 179.) At Dendera, this character is accompanied by the epithet God, and without any female termination, as well as in several passages of an epistolographic manuscript sent home by Mr Bankes; a circumstance which is favourable to the opinion that Ioh was considered as masculine in mythology as well as in grammar, just as Men or Lunus was sometimes made masculine by the Greeks and Romans; the fact, however, is not absolutely decisive of this question, since the character is not accompanied by the delineation of any personification of the deity.

11. The historical description of the god Thoth, or Hermes, as the scribe, or secretary of Osiris, and the inventor of writing, sufficiently identifies him with the person who is perpetually represented standing before Osiris, and writing with a quill or a style on a square or oblong tablet. He has always the head of an ibis, and this bird, standing on a perch, constitutes his hieroglyphical name, as the ibis is known to have been the emblem of Thoth; the hieroglyphic for letters, N. 103, is also frequently found among his titles; and all these circumstances abundantly confirm the opinion of his true character, which Zoega and others have already advanced from conjecture only. The enchorial name is much disfigured, but the manuscripts exhibit a character which may serve to supply the connecting link, and another abridgment of the name which deviates still more widely from the original, being simply the common substitute for a feather, which here seems to stand for the whole bird, or perhaps merely for a feather which is often found projecting from the end of the perch. Next to Osiris, we find that Thoth is of more frequent occurrence than any other deity in the great ritual; and it is probable that the mummies of the ibis, which are so commonly found, were preserved in honour of him. The semicircle with two oblique dashes, under the perch, seems to correspond to the epithet "great and great" of the Rosetta inscription; this character being generally significative of a dual. The scale, with eight dashes, and two other characters, is also very frequently employed as an epithet, and sometimes as a synonym of Thoth; it seems to mean "dispenser of the eight treasures, or laws of the country;" for Diodorus informs us that the principal laws of Egypt were contained in eight books.

12. The name of Osiris is found, with the epithet "divine" in a great majority of all the mythological inscriptions that have yet been discovered; so that this circumstance alone is sufficient to show that it must have been that of the principal deity of Egypt. The enchorial character of the inscription of Rosetta is readily identified, and it agrees perfectly well with that of the manuscripts, answering to the eye and the throne; so that the manuscripts here completely supply the want of that part of the stone which contained the name in the sacred character. This name is also universally annexed to the great figure which is found at the end of almost all the manuscripts, and on the coffins of mummies, holding a hook and a whip or fan, and of which the small detached images are also extremely common. In the sculptured inscriptions, the eye generally precedes the throne; in the running hand of the manuscripts, and on the coffins of some mummies, apparently of later date, the eye sometimes follows. Plutarch had perhaps been rightly informed respecting this character, but by a mistake, which was easily committed from a want of perfect recollection, he has called it "an eye and a sceptre;" and this combination has not been recognised as the name of a deity, though a symbol something like it occurs in some of the tablets. The pictured delineation of Osiris has indifferently a human head or that of a hawk; but never that of any other animal. The tear, N. 100, seems also sometimes to have been used as an emblem of Osiris, as well as of Apis and Mneuis, who were considered as representations of him. The name is found perpetually on monuments of all kinds as an epithet of a departed person; and this is one great reason of the frequency of its occurrence.

13. Arueris, the Apollo of the Egyptian mythology, is sufficiently identified by the comparison of various inscriptions with the fragment of Hermapion, preserved by Ammianus Marcellinus, as the translation of the inscription on a particular obelisc, with which, however, it does not exactly agree, although its style completely resembles that of the Egyptian inscriptions in general, and the beginning corresponds perfectly well to the beginning of almost all the obeliscs in existence, supposing only the hawk to be part of the name of Arueris; which is, besides, an inference extremely probable, from the tablets of several of the obeliscs, representing a deity characterized by a hawk with two bars, and styled the son of another personage who seems to be the sun, as Apollo is called by Hermapion, and Arueris by Plutarch. Mr Hamilton has also given us a Greek inscription at Ombos, in which Arueris is made synonymous with Apollo; although the hieroglyphics which have been copied from this temple, afford us no assistance in the inquiry. The sort of ladder, which occurs as a second name of Arueris, is found prefixed to the hawk in its usual form, on the obelisc at Wanstead figured by Gordon, and on the frize of Montagu and Ficoroni (*Hierogl. Eg. Soc.* 7 Eo p: 9 Lk); and it follows it on a statue of Pococke (Vol. I. p. 212). Arueris is commonly represented either with a human head, or with that of a hawk, bearing a disc, as that of the sun is also generally depicted; and in Plate 138 of Denon, the two deities seem in some measure confounded. The Egyptian name may be interpreted "evening sun," as emblematic of the repose of victory; ER RUHI RE.

14. Isis, the sister and wife of Osiris, is very naturally denoted by the throne with the female termination; and, in more than one instance, the female figures, which have been long recognised as representations of Isis by other attributes, are distinguished by bearing the throne on the head, which is a common

mode of characterising the different personages of the tablets. The manuscripts, again, enable us to discover the connecting link between the sacred and enchorial characters, and to supply the defects of the stone of Rosetta; though the resemblance is somewhat too imperfect to have satisfied us without their assistance. The goddess, thus distinguished, is very generally represented as standing at the head or feet of a corpse, with another female figure opposite to her; and we find the same personages at the opposite ends of several of the sarcophagi; so that the analogy of Isis to Proserpine, and her character as the guardian of the remains of the dead, are sufficiently consistent with these representations. On a scarabaeus, brought from Egypt by Mr Legh, and in a hieroglyphic inscription at Philae, she appears to be called the offspring of Phthah. She often bears in her hand a sceptre forked at the foot, with a lotus for its head, while Osiris has more commonly a similar sceptre with the head of an animal; but these attributes are sometimes assigned to other deities. In one of the boats on the green sarcophagus, and on Letheuillier's mummy, both in the British Museum, she is personified as a basilisc. Mr Hamilton has published some Greek inscriptions from Philae, and from the small temple at Dendera, which show that Isis was the principal deity of these temples; and the hieroglyphics, as far as they have been copied, are precisely of the same import. The great temple at Karnak seems also to have been dedicated to Isis, and probably the small southern temple. On a medal, of Greek workmanship, in the Borgian Museum, we have a figure of Isis, with the word THĒSI, which may probably have been intended for TIESI, the Egyptian name with the feminine article.

15. The constant companion of Isis can be no other than NEPHTHE; her name somewhat resembles that of Isis, with a scale or basin annexed to it, but the square surrounding the throne is completed, and the scale is sometimes detached from it, with a circle interposed; and, in this form, the name comprehends one of the characters denoting a temple. (N. 87.) It seems also to be a head of Nephthe that is found at Dendera and elsewhere, supporting a little temple or shrine, in the place of the capital of a column; nor is it improbable that the great temple at Dendera was dedicated to Nephthe; for the Greek inscription has Aphrodite, which is mentioned by Plutarch as a synonym of Nephthe. It is true that the birth of Isis is represented on one of the ceilings; but it does not, therefore, follow that Isis was the principal goddess of the temple. A head bearing a shrine is not an uncommon ornament of a sistrum; and this agrees perfectly with the remark of Plutarch, that the head of Nephthe, as well as that of Isis, was sometimes represented on these instruments.

16. The emblem of a bird in a cage, which is often found in the manuscripts, accompanied by the figure of a child, seems to indicate the character of a *nurse*, and may without inconvenience be interpreted as relating to the goddess *Buto*, the nurse of Horus and Bubastis; though it would perhaps have been more correct to engrave the name in smaller letters, as denoting some degree of uncertainty. On the sarcophagus called the Lover's Fountain, in the British Museum, she is delineated with a hawk's head; in the western temple at Philae she has a human head with a horned head dress, and she sits near Isis and Horus; a circumstance which strongly confirms the propriety of the denomination.

17. The enchorial name of HORUS seems to be derived from the figure of a hawk followed by the character denoting Isis; an arrangement which agrees very well with the supposition that his usual denomination was HORSIESI. The figure of the infant (N. 133), the chain, and the knot, clearly form a part of the name on a Horus engraved by Montfaucon (*Ant. Expl.* II. p. 302), and on an obelisc from Bosc in the Supplement of the same work. In some cases a feather, following the infant, seems to supply the place of the bird, as in Caylus, Recueil, IV. Pl. 13.

18. PAAMYLES, mentioned by several authors as the Priapus of Egypt, is sufficiently distinguishable by his usual attributes. He is often figured with one hand only, which is elevated towards the angle of a kind of whip or fan, suspended above him. At Edfou he is once denoted in an inscription by a figure like that of the tablets; and in another place by a distinct name, much resembling that of a female deity, found on some of the cases of the mummies, who might consequently be called *Paamylia*.

19. The Nile seems to have been reckoned among the deities of Egypt, and the character which appears to be appropriate to a river (N. 82) is found occasionally in the tablets, followed by a vessel and a spiral (N. 7 or 9, and 201), which seem indeed to make a part of the name, and accompanied by epithets of respect. This character has already been considered by Kircher and others as representing a Nilometer; and the deity in question can only be distinguished by the name NILUS.

20. The sacred characters denoting APIS are pretty clearly determined by the triple inscriptions; the enchorial name is perfectly so. If, however, any doubt remained on the subject, it would be removed by an examination of the inscriptions on four vases found by Paul Lucas (*Voyage dans la Turquie*, 2 v. 12. Amst. 1720, Vol. I. p. 346) at Abousir, the Busiris of the ancients; that is, the BE OSHIRI, or sepulchre of Osiris, as Diodorus very properly translates it. There is a received tradition that Apis was worshipped and buried here, and Lucas established its truth by finding the mummy of a bullock in the catacombs. Now, all the inscriptions on the vases end with a bullock, preceded by this character, though the angles are turned in a different direction from those of the inscription of Rosetta; so that the two forms of the character seem to have been used indifferently. With this latitude, we have no difficulty in identifying the name as it occurs in almost every line of the inscriptions on the great sarcophagus of granite, formerly at Cairo, called the Lover's Fountain, and now in the British Museum; which, there is some reason to suppose, from the frequency of this name, may have been intended for receiving a mummy of the bull Apis; although it must be confessed, that, in several other monuments, the names of the deities are introduced in a manner

somewhat similar, with an evident relation to the designation of some human being, whom they are intended to commemorate.

21. The enchorial name of Mnevis is very completely ascertained by the inscription of Rosetta: and from a comparison of different passages in the manuscripts, there is reason to infer, that it was intended as an imperfect representation of a basilisc and a tear, emblems which are repeatedly found in the great ritual, connected with the figure of a bullock.

21* The sacred cow, in the manuscripts sent home by Mr Bankes, is denoted by a serpentine line with two dots, followed by the term Goddess. We may venture to distinguish her by the temporary name *Damalis*: that of Io would imply too great identity with the Greek mythology. (Plate LXXVIII. L.)

22, 23. In the tablets representing the judgment of the deceased, we generally find two personages standing by the balance, and apparently weighing his merits; one with the head of a hawk, the other with that of a wolf; seeming to officiate as the good and evil genius of the person. The former, denoted by a hawk with a bar, and sometimes also a spear, appears, from various monuments, to have some relation to the sun or to Horus, and may therefore be called *Hyperion*: the other is often observed to be employed in the preparation of a mummy, and may be called from this occupation *Cteristes*, or the embalmer. He is also frequently represented on the coffins of mummies, and elsewhere, under the form of a wolf, sitting on a kind of altar: and he seems to be an immediate minister of Osiris. His hieroglyphical name is a feather, a wavy line, and a block; or a hatchet under a sort of arch.

24 . 27. Under the bier on which a mummy lies, and in many other situations near the person of the deceased, we find representations of four deities who seem to be concerned in the operation of embalming, and who might even be supposed to preside over the different condiments employed, their heads frequently serving as covers for four jars, of the kind sometimes called Canopi: they may also very properly be considered as attendants of Isis, who seems to be a still more important personage on such occasions. The first of the four has generally a human head, and may be called *Tetrarcha*; his name contains a sort of forceps, and a broken line: the second and third have respectively the heads of a dog or baboon and of a wolf: and they agree very satisfactorily with the well known character of Anubis, and with that of Macedo his companion, mentioned by Diodorus as having a wolf's head, whose name may possibly have some relation to manchat, "a worker in silver," as that of Anubis has to nub, "gold." The hieroglyphic name of Anubis differs from that of Apis only in having the angles directed immediately upwards, a circumstance which is not so indifferent to the signification as it at first appeared; that of Macedo has a vulture with a star, and sometimes an arm instead of the vulture. The fourth of these deities is represented with the head of a hawk, and may therefore be called *Hieracion*: and he is denoted by a water jar, with three plants, somewhat resembling leeks or onions.

28 . . 32. Among the many hundreds of deities who are represented in various inscriptions and sculptures, some of the most remarkable are two personages with the heads of wolves, the first characterized by a sort of raised frame or banner, and a pair of horns, which may be expressed by the pseudonymous or temporary term *Cerasochus*, and the second by a half bow, and a sword or knife, whence he may be called *Bioxiphus*; a figure with a human head, generally wearing a feather on it, and denoted by a broad feather reversed, which is implied in the name *Platypterus*; another wearing a cap with a whip in it, who may be called *Mastigias*; and a fifth in the form of a female, distinguished by a bier, who, at Edfou, bears a tear on her head, and who may be called *Soraea*.

B. KINGS.

33, 34. We are informed by Pliny, that the *Alexandrian* obelisc was erected by Mesphres or Mestires, the reading of the different manuscripts being different; and since no king of the name Mestires is mentioned by other authors, we may consider this *Mesphres* as the Mephres or Mesphris who succeeded his mother Amersis about 1700 B. C., or perhaps a century or two later. The hieroglyphical name of his father contains that of the god Thoth, and may therefore possibly have been intended for the *Thuthmosis* of the chronologers, who is said to have been the grandfather of Mesphres. The obelisc at Alexandria, now called Cleopatra's Needle, like almost all others which contain three lines on each side, exhibits different names in the middle and the outer lines; from this circumstance, as well as from the greater depth of the sculptures, which is generally observable in the middle line, there is reason to suppose that this line stood at first alone, and that the two on each side were added by a later monarch. The *Lateran* obelisc, however, is remarkable for exhibiting the name of Mesphres on all the lines of the different sides. The *Constantinopolitan* obelisc has only one line on each side, with the name of Mesphres, the son of Thuthmosis. The same name is also found on the gateway of the fifth catacomb, at Byban El Molouk: on a pillar of the palace at Karnak, and in a spendidly coloured bas relief on one of the interior architraves of the gallery; as well as on a seal of Denon, Pl. 98, and on some others brought from Egypt by Mr Legh.

35. The *Isean* obelisc of Kircher has a "son of Mesphres, favoured by Phthah;" we must therefore distinguish this king by the name *Misphragmuthosis*, who is recorded as the son and successor of Mesphres.

37 . . 39. A multitude of ancient Greek inscriptions identify the statue of Memnon, celebrated by all antiquity for its musical powers, which, Strabo says, he witnessed in person, though he could not very positively decide that the sound proceeded from the statue, rather than from some of the bystanders. In one of the inscriptions we find the word *Phamenoth*,

not as a date, but as a synonym of Memnon, which must be considered as identical with the Phamenoph given by Pausanias as his Egyptian name, and with the Ammenoph or Amenophis of Manetho or others, which differs from it only as wanting the article. There is, however, some doubt to which Amenophis this statue properly belongs. Manetho makes Memnon the eighth king of the eighteenth dynasty, who may be called Amenophis the second; but Marsham brings him down to the Ammenephthes of Manetho, or Amenophis the Fourth, and principally because he thinks that only a successor of Sesostris could have been well known in Asia; and he even supposes him to have been later than Homer, who, he says, never mentions him, though Hesiod calls him the son of Tithonus and Aurora. But, in fact, the name of Memnon does occur in the Odyssey, where Ulysses alludes to his beauty in a conversation with the shade of Achilles; and Hesiod could scarcely have mentioned a king as descended from a deity, that was not considerably earlier than his own time; so that the tradition of Manetho seems to be preferable to the mere conjecture of Marsham. At the same time, we cannot well call him Memnon, the son of Thuthmosis, the name of the father not agreeing with that of this king; and there is another circumstance, which seems to lead us to the third Amenophis, intermediate between these two extremes, who was the son of Ramesses Miamun, or Ramesses the lover of Ammon; which is, that Amenophis himself appears to have built a temple to Ammon in the isle of Elephantine, and is called Miamun in several of the hieroglyphical inscriptions still existing there; so that there is little doubt that the name Memnon must have been derived from Miamun. Besides the different statues of the Memnonium, we find monuments of the same personage in almost every part of Egypt, though they are much more frequent at Thebes and in its neighbourhood. The name is marked on all the lion headed goddesses of black granite which are now in the British Museum, and on some others which are in possession of Mr Bankes. The first of this series having been purchased, as Bruce informs us, for a large price, by Donati, for the King of Sardinia, the inhabitants were induced to take some pains in digging the others out of the sand. The building, called by the French the tomb of Osymandyas, bears also the name of Memnon; and it is remarked by Strabo, that Memnon and Ismendes may probably have been the same person. The name is also found in the grottos at Byban El Molouk, on some statues representing Osiris and in some inscriptions at Ombos, as well as on a seal of Denon, Pl. 98. Mr Bullock has presented to the British Museum a scarabæus of very hard stone, on which we find the name of Memnon, together with that of his father and mother, whom we may call, in order to preserve the mythological analogy, *Tithous* and *Eoa*, although without asserting that this Tithous was the builder of the labyrinth, which some authors have attributed to a king named Tithoes, and others to Ismendes. The mother's name occurs also alone, as "the goddess mother," on the back of a beetle in Gordon's Mummies, Plate 22; a circumstance which removes the doubt, that might otherwise arise, from the want of the female termination in the name; the father's is found on a square seal, in the possession of Mr Legh. There is another copy of the inscription of Mr Bullock's scarabæus, on a scarabæus belonging to Mr Palin, which had long been used by a Greek priest at Athens, for stamping the paschal bread. (*Dubois*, Pierres Gravées, Par. 1817, Pl. V. N. 5.) The beautiful head, lately brought from the Memnonium to the British Museum, has only a part of the father's name remaining, which does not appear to be that of the father of Memnon, though the first three characters are the same; but the fourth is the pedestal representing Phthah; and a similar name is found on some other colossal statues and obeliscs remaining in Egypt, as well as on a smaller figure of red granite, brought by Mr Hamilton from Elephantine.

39. In the principal name on the obelisc at *Karnak*, the final scale of the name of Memnon is exchanged for a pair of arms stretched upwards; a variation which may be expressed by calling it Amenuses or *Amenses*, from SHESH, a pair. The father's name is also a little like that of Tithous; but, that the difference is constant, may be inferred from its separate occurrence on a seal brought home by Mr Legh, a lion's head making a part of it in both instances. The true name and date of this personage must be considered as wholly unknown, though the resemblance of the name to Memnon makes it convenient to place them together. In Mr Boughton's minute golden image, engraved in the Archæologia, the name appears to be the same, but with the synonymous substitution of the hatchet for the judge.

40, 41. The obelisc at *Heliopolis* has every mark of considerable antiquity, and the shortness and simplicity of its inscription is appropriate to a remote period. Pliny says, that Mitres or Mestires first erected obeliscs at Heliopolis; he also mentions Sothis, and apparently Ramesses, as having left similar monuments of their magnificence in the same place. The principal name on the obelisc now remaining at Matareah may also be observed in several other inscriptions, but with the substitution of two other names for that of the father; so that the name of the son must probably have belonged to many different individuals; a circumstance which, as well as the sounds belonging to the different characters, agrees very well with Ramesses, for we have RE, "the sun," MES, "a birth," and SHESH, "a pair;" so that we may venture to call it *Remesses*; and we may take *Heron* for the father of the first Remesses, from Hermapion though it is possible that he may be the Armais of Manetho; but we have scarcely sufficient evidence to appropriate to him that name. Another Remesses seems to have been a son of Sesostris; a third Ramesses follows Ammenephthes in Manetho, and agrees with the Rhampsinitus of Herodotus, and the Remphis of Diodorus, who is mentioned as the successor of Proteus; and this may, perhaps, have been the Remesses of the frizes of Montagu and Ficoroni (Hierogl. 7 Ou. 9 If), who seems, from the resemblance of the different parts of the work, to have been nearly contemporary with Sesostris. (Hierogl. 7 H. I.) There is also another Remesses on the Lions at the fountain of Aqua Felice, near the baths of Diocletian at Rome, the name of whose father is a little like the name supposed to belong to Arsinoe, N. 60.

42, 43. The obelisc erected by Augustus in the *Campus Martius*, is said, by Pliny, to have been the work of Sesostris; and there are sufficient documents of its identity with that which had long remained buried near the Monte Citorio, and of which figures have been given by Zoega and others. The inscription was supposed, in the time of Pliny, to contain a compendium of the physical and philosophical learning of the Egyptians; but, in order to make this opinion credible, it would be necessary to admit that the princes of earlier days entertained very different ideas from those which have since been prevalent, respecting the comparative importance of the abstract sciences, and of national prosperity, and martial glory. If Sesostris was the son of Amenophis, he cannot have been the reigning king mentioned in this obelisc; but it may safely be attributed to *Pheron* the son of *Sesostris*, who, according to Herodotus, erected two obeliscs; and the occurrence of the name of Sesostris, as the father, may be considered as sufficiently conformable to the testimony of Pliny. The same names are found, with a slight variation, on a small statue of basalt, very highly finished, now standing in the British Museum; and Denon has copied them from an inscription in the Memnonium. (Pl. 118.)

44. *Nuncoreus*, according to Diodorus, was another son of Sesostris; his name occurs also in Pliny, and we may consider him as the son of Sesostris mentioned in Mr Montagu's frizes. The name is also found at Philae, and, with a slight variation, on an altar of basalt, figured by Caylus (Rec. I. Pl. 19), now in the king's library at Paris. The remains of the same name may also be observed on a block, apparently of white sandstone, in the British Museum, which is figured by Norden, in its old situation, as a part of the foundations of Pompey's Pillar at Alexandria, and it occurs on a fragment of a statue brought by Mr Hamilton from Thebes.

45. The name of *Proteus*, or Certus, otherwise Ammenephthes, is only known as the predecessor of one of the kings named Ramesses, and we may safely employ it for the father of the Remesses of the frizes of Montagu and Ficoroni, the whole of which are remarkable for the excellence of their workmanship.

46, 47. Until we obtain evidence of a more positive nature, we may give to the two kings mentioned on the sarcophagus of green breccia, the names of *Amœnupthes* and *Anysis*, supposing them to have lived about the time of Amenephthes, or Amenophis the Fifth, and his successor Osochon. The father's name might, without difficulty, be read "Mænuphthah," supposing some titles to follow it. There are also two obeliscs of the same king, brought from Cairo, which stand near the sarcophagus in the British Museum, and the style of the workmanship somewhat resembles that of the times of Sesostris, and his immediate successors. It has been observed, that neither of the names can well be Alexander's, since that of the father is repeated much more frequently than that of the son, which could not have happened if it had been meant for Philip; and Alexander had no son who could have been mentioned in his sarcophagus. Nor is it at all probable, that Alexander should have erected any obeliscs at Memphis or in its neighbourhood. The god Ammon is no where mentioned among the titles of the king, and holds only an inferior rank among the innumerable deities represented in the tablets. We find both the names, without any addition, on a dovetail of copper, engraved in Lord Valentia's *Travels*, which was found at Behbeit, the Atarbechis or Aphroditopolis of the ancients, situated on the branch of the Nile that runs to Damietta.

48 . . 50. We learn from Pliny, that the *Flaminian* obelisc, now standing near the Porto del Popolo at Rome, which was the smaller of the two formerly in the Circus Maximus, placed there by Augustus, and used as the gnomon of a dial, was the work of Sennesserteus or Semnesyrtaeus, who reigned in Egypt at the time that Pythagoras visited it. This king seems to have been the same with Psammuthis or PSAMMIS; and the authority of the evidence is so much the stronger, as the period in question is not extremely remote. The father of Psammis, according to Herodotus, was Necos or NECHAO The two names occur on all the middle lines of the obelisc; and that of the father on the pillar of a colossal Isis in the Supplement of Montfaucon: the *Sallustian* obelisc, which seems to have been partly copied from the Flaminian, has them both. In the middle lines of both the obeliscs at *Luxor* we find a name much resembling that of Psammis, which we may therefore call *Psammetius*, conjecturing that it may have belonged to Psammetichus, who reigned a little earlier: the father's name is not unlike in its import to that of Nechao, both implying "approved by Phthah;" and it is remarkable, that in Manetho's series, the predecessor of Psammetichus is also Nechao.

51, 52. Among the most common of all the names of the kings of Egypt on a great variety of monuments, are those which were mistaken by Kircher for a sort of amulets or charms, which he denominated the Mophthomendesian tablets. They occur alone on three small obeliscs only, the *Medicean*, the *Mahutean*, and the *Monticœlian* of Kircher; but they are found in the external lines of the Alexandrian, the two at Luxor, the Flaminian, and the Sallustian, while none are ever found exterior to them. They must, therefore, necessarily be attributed to one of the latest kings of Egypt; and there is none so likely to have made such a display as AMASIS, a man of considerable magnificence, and at the same time of a cautious and artful character: indeed, we have no alternative left but to choose between him and some of the kings who revolted against the Persians, and who do not appear so likely to have had leisure or finances for public works of splendour. His father's name, like that of Nechao, contains the character denoting Vulcan, and it may be called *Macnuphthes*; but he was not the son of a king. Both the names are found in one of the middle lines of the Flaminian obelisc; and on that side the king is represented in the tablet as doing homage to his predecessor, who occupies the place of honour on the other sides. The father's name seems to occur on the belt of a colossal statue in the palace at Karnak. On a fragment of stone in the British Museum, the names are repeated in various directions, as if it had belonged to a floor or a ceiling: they also occur on a statue, considerably mutilated, in the attitude of kneeling; and in Montfaucon's Supplement, on the back of a colossal Isis, which seems also to have been begun by Psammis. On the eastern colossus at Luxor, there is a name which might be taken either for that of Amasis, or for that of the pseudonymous Psammetius; but the sitting figure is somewhat different: the victor in the naval combat at Medinet Abou, who appears also frequently at Ombos, considerably resembles them both. Lord Mountnorris has a rough seal with the name of Amasis only, the epithet God being prefixed in a smaller character. The names also occur on a small obelisc lying at Tsan, the ancient Tanis, of which a sketch was brought home by Dr Merion.

53, 54. We find at Karnak the name of a king somewhat like Psammis, that of his father resembling a compound of Ptolemy and Berenice. Perhaps they are not very correctly copied, but they may stand, under the temporary names of *Discozygus* and *Ptoleberius*, as specimens, somewhat singular, of a mixture of different dynasties; and in this point of view they may be placed between the old Egyptian kings and their Grecian conquerors.

55. (Plate LXXV.) The name of ALEXANDER has not yet been identified in the sacred characters; but it will appear hereafter, that a knowledge of the enchorial form may possibly contribute very materially, at some future time, to assist us in determining it.

56. There can be no doubt whatever respecting the signification of the name of PTOLEMY, as it occurs on the stone of Rosetta; but it is not quite so easy to determine its identity in some other cases, where it may possibly have been modified by contraction, mutilation, or combination. In this and a few other proper names, it is extremely interesting to trace some of the steps by which alphabetical writing seems to have arisen out of hieroglyphical; a process which may indeed be in some measure illustrated by the manner in which the modern Chinese express a foreign combination of sounds, the characters being rendered simply "phonetic" by an appropriate mark, instead of retaining their natural signification; and this mark, in some modern printed books, approaching very near to the ring surrounding the hieroglyphic names. The enchorial name of Ptolemy appears at first sight to be extremely different from the hieroglyphical; and it would have been impossible to deduce the one from the other, without a knowledge of the epistolographic forms of the separate characters, as ascertained by a comparison of the manuscripts. The beginning and end are obviously parts of the ring, which, in the sacred character, surrounds every proper name except those of the deities. The square block and the semicircle answer invariably in all the manuscripts to characters resembling the P and T of Akerblad, which are found at the beginning of the enchorial name. The next character, which seems to be a kind of knot, is not essentially necessary, being often omitted in the sacred characters, and always in the enchorial. The lion corresponds to the LO of Akerblad; a lion being always expressed by a similar character in the manuscripts; an oblique line crossed standing for the body, and an erect line for the tail; this was probably read not LO but OLE; although, in more modern Coptic, OILI is translated a ram; we have also LIUL, a stag; and the figure of the stag becomes, in the running hand, something like this of the lion. The next character is known to have some reference to "place," in Coptic MA; and it seems to have been read either MA, or simply M, and this character is always expressed in the running hand by the M of Akerblad's alphabet. The two feathers, whatever their natural meaning may have been, answer to the three parallel lines of the enchorial text, and they seem in more than one instance to have been read I or E; the bent line probably signified great, and was read OSH or OS; for the Coptic SHEI seems to have been nearly equivalent to the Greek SIGMA. Putting all these elements together, we have precisely PTOLEMAIOS, the Greek name; or perhaps PTOLEMEOS, as it would more naturally be called in Coptic. The slight variations of the word in different parts of the enchorial text may be considered as expressing something like aspirations or accentuations.

57. The appellation SOTERES, as a dual, is well marked in the inscription of Rosetta, and the character, thus determined, explains a long name in the temple at Edfou, which must mean "the two saviour gods," with various titles of honour, such as "the agents of Phthah, the emblems of triumph, the approved of Phre, the favoured of the Nile, the venerable consorts in empire."

58. The wife of Ptolemy Soter, and mother of Philadelphus, was BERENICE, whose name is found on a ceiling at Karnak, in the phrase, "Ptolemy and . . Berenice, the saviour gods." In this name we appear to have another specimen of syllabic and alphabetical writing combined, in a manner not extremely unlike the ludicrous mixtures of words and things with which children are sometimes amused; for however Warburton's indignation might be excited by such a comparison, it is perfectly true that, occasionally, "the sublime differs from the ridiculous by a single step only." The first character of the hieroglyphic name is precisely of the same form with a basket represented at Byban El Molouk, and called, in the description, "panier à anses;" and a basket, in Coptic, is BIR. The oval, which resembles an eye without the pupil, means elsewhere "to," which in Coptic is E; the waved line is "of," and must be rendered N; the feathers I; the little footstool seems to be superfluous; the goose is KE, or KEN; Kircher gives us KENESOU for a goose; but the ESOU means gregarious, probably in contradistinction to the Egyptian sheldrake, and the simple etymon approaches to the name of a goose in many other languages. We have, therefore, literally BIRENICE; or, if the N must be inserted, the accusative BIRENI-

CEN, which may easily have been confounded by the Egyptians with the nominative. The final characters are merely the feminine termination. The enchorial text affords us a remarkable instance of the diversity which was allowed in the mode of representing the same name. The first character has not the least resemblance to the basket; but the first and second together are very commonly used in the manuscripts, as a coarse representation of a boat, which was called BARI, or possibly BERE, for it is doubtful whether Kircher had any other authority than that of Diodorus for Bari; and the word BEREZOYTS is used for another vehicle. The enchorial N may possibly have been derived from a horizontal line, turned up at one end; we have then the three dashes for the I, and the two angles seem to have answered to the KE, for a bird is not uncommonly scribbled in some such manner; so that we have either BARINICE or BERENICE, by a combination somewhat different from the former.

59 . . 65. The temple at Ombos was dedicated, as we find from the Greek inscription copied by Mr Hamilton, "in the name of the divine Ptolemy Philometor and Cleopatra, and their children, to Arueris Apollo, and the other gods of the temple, by the infantry and cavalry of the nome." We may, therefore, expect to find in it the names of these sovereigns, together with those of some or all of the earlier Ptolemies; and, accordingly, we are able to determine, without difficulty, some epithets which seem to be characteristic of this and the two preceding reigns; but, hitherto, nothing has been observed that can be considered as so clearly denoting either Philadelphus and his queen Arsinoe, or Euergetes and his Berenice, although some assistance might have been derived, in identifying them, from the enchorial text of Rosetta. We have, however, in the same temple, a name, evidently compound, in which a basilisc is followed by two feathers and a bent line; and to judge from a comparison of the enchorial text with the manuscripts, a basilisc ought to be the emblem of EUERGETES; the part of the name preceding it is, however, not Berenice, and must, therefore, in all probability, be ARSINOE, the daughter of Euergetes. But it seems impossible to attempt to compare the characters employed with the sounds; since they sometimes occur in an inverted order, which the sounds could not do. Indeed, the name seems to be very often repeated in situations where its most essential parts seem to be a quadrant of a circle, two feathers, and a bent or broken line; in other places, as at Dendera, the bird, the hand, and the oval, are added; and it is not impossible that the quadrant may have been meant as a representation of a lentil, which in Coptic is ARSHIN, and which alone may have been sufficient to identify the name. It occurs in the celebrated zodiac at Dendera, and very frequently at Philae, and it may, possibly, hereafter, lead us very readily to discover the hieroglyphical name of *Philadelphus*. That of PHILOPATOR is satisfactorily ascertained by the assistance of the character employed for "father" in the Rosetta stone, though that character is much mutilated, and could not have been positively determined without this coincidence. The name is found in the *great* temple at Edfou still more distinctly than at Ombos, and it occurs several times at Karnak. EPIPHANES is never distinguished in any other inscription by the characters appropriated to him in that of Rosetta N. 121); but we continually find a synonymous emblem, which is employed in the Rosetta stone to signify "enlightening," where the Greek translation has EPIPHANES; and this character, placed between two hatchets facing each other, can only have meant the "illustrious deity," or deities. In this form, the name occurs very frequently at Philae, and in the great temple at Edfou, where it seems to be the latest name. For the PHILOMETORES, we have a character which occurs in some other monuments, and means apparently "mother," the name containing it being found several times in the temple at Ombos. At Kous, or Apollinopolis Parva, there is another Greek inscription of the Philometores and their children; but in the hieroglyphics copied by Denon, the names of the sovereigns seem to be wanting, and that of a young prince only remains, a colossal statue of whom is figured by Montfaucon in his *Supplement*, having the same name in the belt, with the addition of "the son of King Ptolemy;" it will, therefore, be justifiable to distinguish this personage by calling him *Cleopatrides*. The divine honours, which are so often attributed in these inscriptions to the reigning sovereigns, afford us an explanation of the Greek inscriptions to the "Synthronous gods of Egypt," which repeatedly occur; and of the description "Fraternal gods," as, indeed, Philadelphus and his queen are called in the Greek inscription of Rosetta.

C. PRIVATE PERSONS.

66 . . 71. We find the names of six individuals expressed in the enchorial text of the inscription of Rosetta, though they are wanting in the distinct hieroglyphics; but, as they are clearly ascertained by the context, they are of considerable value in tracing the approach of the hieroglyphic to alphabetic writing. These are AETOS, PHILINUS, DIOGENES, PYRRHA, AREIA, and IRENE. In Diogenes and Areia, we discover no traces of the ring which is the usual characteristic of proper names: and on the other hand, we find occasionally, in some of the manuscripts, the parts of the ring applied to a title of Osiris, which is more regularly written without any such distinction.

72. A name of a private individual is inserted from a sarcophagus in the British Museum, engraved by Alexander, in his *Egyptian Monuments*. Its form is not that of a parallelepiped, but more accommodated to the shape of the body. The pseudonymous appellation *Ramuneus* has been derived from the elementary characters already observed in the names of RE and AMUN.

D. ANIMALS.

73. A figure sitting on the ground, and stretching out one hand, seems to imply simply a MAN or person; which is certainly the sense of the enchorial

character that commonly answers to it in the manuscripts; but in composition the figure often appears to lose this sense.

74. The horned snake, creeping along, is clearly meant, in some parts of the inscription of Rosetta, for HIM or IT; although it has other senses in composition. It is very remarkable, that the enchorial character, and that of the manuscripts, resembling a *y*, approaches extremely near to the Coptic F, which also means "him;" and HOF, or HFO, is the Coptic term for a snake; so that this coincidence seems to afford us another trace of the origin of the alphabet.

75 . . 78. The BULLOCK, the RAM, the ANTELOPE, and the TORTOISE, are proved to be sometimes representations of the things which they resemble, by their occurrence in inscriptions accompanied by tablets; though some of them have probably, elsewhere, a metaphorical sense. The ram is often represented with two pairs of horns; the one natural, the other imaginary.

78*. The CROCODILE is identified by a very distinct drawing in a manuscript sent home by Mr Bankes, and is repeatedly designated in the text by a figure representing it. (a) The deity with a crocodile's head is a separte personage, and is denoted by a figure of the same animal with the tail turned under it. (b) Plate LXXVIII. (L)

79. The asp or BASILISC is so coarsely represented in the stone of Rosetta, that the object intended by it could not have been conjectured without a comparison with other inscriptions; the context was, however, sufficient to determine its meaning from the examination of this monument alone.

E. INANIMATE OBJECTS.

80. The essential parts of the name of EGYPT seem to be the square and the wheel, signifying "splendid land." In addition to these, or their rudiments, the enchorial word has at the beginning a character which generally answers to an arm holding a feather, or to the flame of a lamp, an emblem which seems also to relate to Egypt in one of the lines of the inscription of Rosetta. A flame and a heart are mentioned by Horapollo and by Plutarch, as employed in the name of Egypt; but a word occurring so frequently is very likely to have been expressed in a variety of ways. The exact combination of characters generally used on the stone, has not been observed in any other inscription.

81. The name of MEMPHIS cannot be determined without some uncertainty; the line of hieroglyphics, in which it is contained, being in several respects obscure.

82. The character, supposed to denote the Nile, as a deity, must also sometimes be understood as merely meaning a RIVER; and there is reason to think that the Nile itself was generally called by the Egyptians "the river" only. The enchorial character, used to denote both the Nile and a river, or canal, sufficiently resembles the hieroglyphic to favour this interpretation; and it is in some degree confirmed by the occurrence of the character alone on a water jar of Peiresc, delineated in Kircher's *Oedipus;* and, together with other characters, on the five vases found by Paul Lucas at Abousir. By accident, Kircher appears, in this single instance, to have been right in one of his conjectures; for he calls this character a Nilometer, and considers it as emblematic of the Nile.

83. The word GREEK, in Coptic UININ or OUEININ, in Thebaic OUEEIENIN, supposed to have been derived from *Ionian*, seems to exhibit in its form something like an imitation of the sound. The curl on a stem is sometimes exchanged for the term *divine*, and appears to mean "glory," in Coptic oou or ou, which is nearly the sound attributed by Akerblad to the enchorial character, a little like the Hebrew U; the feather, as in Ptolemy and Berenice, may be read I or EI, having the three dashes to express them, as usual, in the enchorial text; the serpent is ENEH, "ever;" and the hat, which looks a little like a plough, is equivalent to the waved line (N. 77), and must be read N; so that we have very accurately OUIENEHN, which seems to be near enough to OUEININ, to justify us in considering these characters as phonotic.

84. The ladder is well marked as meaning COUNTRY; it may perhaps be intended to represent a field with its divisions; but it is uncertain whether or not it is the same symbol that enters into one of the names of Arueris (N. 13), the sculptures of the Rosetta stone being by no means highly finished

85. It is remarkable, that the wheel, signifying LAND, had been noticed by the Jesuits, as resembling the old Chinese character for the word *field* but this is the only one, of a multitude of similar conjectures, that has been justified by more complete evidence. (*Phil. Trans.* 1769. Pl 28.)

86. The star is shown to relate to a real STAR, by inscriptions accompanying the zodiacs. It has also elsewhere, a figurative sense, meaning an attendant or *ministering spirit*.

87. The open square is found in both the combinations of characters, which are most commonly used for expressing a TEMPLE; the feather signifies ornament or consecration; the oblong figure, either the sacred inclosure or a sacred seat, the character for a god being sometimes placed within it. The feather is occasionally converted into an inclined oval, the square being at the same time a little altered; a difference which may be observed in other inscriptions, as well as in the Rosetta stone.

88. The character representing a SHRINE so much resembles the object which it denotes, that it was the most readily identified of all that are found on the stone of Rosetta. The character signifying a priest was the second; and the combination of both afforded a full confirmation of the truth of the explanation. The enchorial character for a shrine is derived from the sitting statue which always accompanies it.

89. The open square, occurring in HABITATION as well as in temple, must probably have meant *house* or building; or possibly stone only.

90. The THRONE, or chair of state, occurs in a great variety of tablets. It evidently bears its most natural signification in the character denoting sta-

Hieroglyphic Vocabulary.

tue, n. 102, and in some other instances; but it appears to bear, in some inscriptions, the metaphorical sense of a residence or habitation.

91. The COLUMN, or pillar, is too much like the object it denotes, to allow us to doubt respecting its meaning, considering the sense of that part of the inscription of Rosetta in which it occurs.

92. The characters denoting a DIADEM are sufficiently determined by the first inscription of the stone; and they so much resemble the corresponding passages of the enchorial text, that we can scarcely hesitate to admit the intimate connexion of the two modes of writing, without seeking for any further proofs.

93. The sacred ORNAMENTS are expressed by three feathers, fixed to a bar, which appears to be held by two arms. The remaining part of the character occurs very frequently as a sort of termination, and seems to answer to .. *ments*.

94 .. 99. The boat or SHIP, the SPEAR, the BOW, the ARROW, the CENSER, and the BIER, are sufficiently identified, by the comparison of various tablets with their inscriptions. The ship occurs frequently as denoting the sacred boats, in which the representations of the deities are conveyed; though they are not always accompanied by water. But it has been observed, that the Egyptians attributed ships rather than chariots to the sun and moon, as gliding smoothly through the skies. The first part of the enchorial word, which has been supposed to be a B, is evidently identical with the character always found in the manuscripts written in the running hieroglyphics, as the first part of the delineation of a ship. It is remarkable, that, in the inscription at Esne, as copied by the French, the point of the arrow is turned towards the back of the bowman, instead of being directed towards the enemy.

100. The TEAR, in some of its representations, is very clearly expressive of the thing intended; and this resemblance, together with its frequent attendance on a corpse and a bier, is sufficient to explain its sense. It occurs also sometimes within a border, as a peculiar deity; but it seems to be much more commonly emblematical of Osiris, of Apis, or of Mneuis. It is not unfrequently found as a detached figure, in a kind of pottery, with a green glazing; and may perhaps have been worn, instead of a mourning ring, as a memorial of a departed friend. It has most commonly been called the *equi sectio*, and supposed to represent a horse's head, or the rostrum of a ship, while the ingenious Kircher has made it a *phallus oculatus*. Among the antiquities collected by Lord Mountnorris in Egypt, is an eye seen in front, and apparently shedding a tear.

101. The character for an IMAGE seems to mean *a wrought man*; the hands, connected with an eye, appear to be holding an oar, as an emblem of *labour*. The same character, with a slight variation in the form of the eye, means a rower, (n. 186.)

102. The sitting STATUE has no character to imply wrought; but it is followed by a bent line, which seems to be a term of respect, and may possibly answer to OSH, "great." The same bent line occurs on the great sarcophagus of green breccia, as a personification of one of the qualities of Osiris, probably *his magnificence*. It is often exchanged in the manuscripts for the divided staff; and both are represented in the running hand by a figure like a 9 or a 4. In the enchorial text this character seems sometimes to be expressed by a single line, either straight, or bent sideways into an angle, like part of a K. A similar "divine statue" is decreed to "King Nuncoreus, the son of Sesostris," on Mr Montagu's frize. Hierogl. 7 S l.

Hieroglyphic Vocabulary

103. LETTERS are denoted by a character which seems to represent some of the materials employed in writing; and which is indeed not extremely unlike an inkstand figured in Caylus's Recueil, and consisting of two parallel tubes at some distance from each other, with a cover connected by a chain instead of a hinge. Besides the very well marked passage in the Rosetta stone, the character occurs in many manuscripts near the representation of a Thoth employed in writing; and the enchorial character, corresponding to it, is also found in the term *sacred scribes* at the beginning of the inscription.

104. In the numerical tablet of the great French work, believed to have been found at Karnak, a character may be observed which frequently precedes a numeral, and which resembles a weight with its handle. Hence we may conjecture, with considerable probability, that it represents some *weight* of unknown value.

105. The enchorial character for GOLD is perfectly well determined; and its resemblance to a little vase under a sort of arch is so strong, that we may safely attribute the same sense to this hieroglyphic, although it appears to be wanting in one or two passages of the sacred inscription of Rosetta, where it ought to be found. In the great ritual, we observe this character immediately preceding a shrine, as if a "golden shrine" were intended; and, in several other places, it is connected with a number, as if it meant *pieces of gold*; for instance, in the green sarcophagus, with the number 360. Sometimes, also, it appears to be used in a metaphorical sense, as a complimentary epithet of a monarch, or perhaps in allusion to his riches. Thus, on the black frize of Nuncoreus, we have, over the king's figure, the characters, "Joy, Life, Stability, Power, *Riches*, Like the Sun for ever." Hier. 7 p.

106. Near to the character for gold, in the margin of the great ritual, is a sort of open box, supported on a flagstaff: and a similar box, with a semicircle under it, seems to mean SILVER: at least it considerably resembles the enchorial character for silver, which is perfectly well ascertained.

107. We find, in several inscriptions, representations of objects which are also observable in the tablets accompanying them, although it is difficult to say for what they are intended. Two of these are copied from the frize of Ficoroni and Montagu, Hier. 9 okl, nakl, 7 LMQ. The former seems to be a sort of cloak, with a fringe at the bottom; the latter is a little like a pear; but this character does not occur so clearly in the inscription.

F. ATTRIBUTES AND ACTIONS. (PLATE LXXVI.)

108. The *crux ansata*, sometimes called the Key of the Nile, is usually employed as a symbol of divinity; but its correct meaning is LIFE, as Lacroze rightly conjectured, although his opinion respecting the origin of the character is inconsistent with the form of its oldest and most accurate delineations; and there is no one instance in which it is so represented as to stand in any relation to a sluice or a watermark. According to Socrates and Rufinus, the Egyptian priests declared to their Christian conquerors under Theodosius, who were going to destroy the Serapeum at Alexandria, that the cross, so often sculptured on their temples, was an emblem of the life to come. This passage has been understood by some authors as relating rather to the cross without a handle, which is observable in some rare instances, and indeed twice on the stone of Rosetta; but this symbol appears rather to denote a protecting power, than an immortal existence. It happens, perhaps altogether accidentally, that one of the contractions for the word *God*, which are commonly used in Coptic, approaches very near, to this character, except that the arms of the cross are within the circle.

109. ETERNITY is represented simply by a serpent rising in an oblique arch, and without horns; the serpent devouring its tail, and making a ring, is never found as an Egyptian emblem. Horapollo says that eternity was denoted by a serpent having its tail hidden under its body; and that such serpents were called URAEI, meaning in Greek BASILISCI, which agrees very well with the sense of the Coptic URO, "king;" but this description answers better to the *asp* of the inscription of Rosetta, which has also some relation to the representations of the deities, though it does not exactly mean immortality.

110. The cross with the serpent is a very common epithet, in the sense of everliving, or IMMORTAL, AEONOBIUS; the waved line is in general a preposition, or a termination, meaning *of*, *to*, or *for*; and it appears to be synonymous with the hat (n. 177). Almost all authors have very hastily taken for granted, that this character must relate immediately to water, wherever it occurs, although we find it repeatedly in every line of the inscription of Rosetta, where water is not once mentioned. The fact, however, is, that its prototype seems to have been a stream of water or of any other liquid, flowing *from* a vessel, and poured *on* some other object; and that the idea of the liquid was completely dropped in the general employment of the character; while that of the *connexion* only was retained; and the [illegible], being also [illegible] forgotten, while its [illegible] the head of the water only was suggested by its figure. In this compound character, we have two [illegible] nearly alike, the semicircle and the [illegible] that they cannot be very different is shown by the [illegible] of two semicircles [illegible] seems to serve for the connexion between the [illegible], "life for ever;" and the other to make the new compound an adjective, "living for ever."

111. The triangle or pyramid occurs very commonly among other emblems of prosperity and happiness; and it is found in the frise of Montagu and Ficoroni, in the decided sense of an offering or a present in general, while, in another place, it is made an offering in its own form; so that we can only interpret it as signifying joy, or pleasure, or prosperity. (Hierogl. 7 Mqr, Uqr; 9 Re, Rl; 7 Uq, Urs.)

112. POWER appears to be indicated by a sceptre having the head of an animal, which is often placed in the hands of the deities, and often stands with the cross, the pyramid, and the altar, as an emblem of the blessings attendant on the favourites of the gods. It is seldom used in the text of inscriptions, but it occurs once in that of Rosetta.

113, 114. STABILITY is denoted, on the Rosetta stone, and elsewhere, by the altar, which seems to have been fixed in the ground as a column. When repeated, it makes the verb ESTABLISH; but it often occurs singly, and not uncommonly as an unconnected emblem, accompanied by other characters of similar import; and it is sometimes found as a detached figure, formed of glazed porcelain. The two altars are very conspicuous objects in some of the epistolographic manuscripts, and are very useful in comparing them with the hieratic; but the word employed in the enchorial inscription of Rosetta seems to be derived from a different origin.

115. A drop or club over a basin, followed by a bent line, seems to mean GREAT STRENGTH; though it is difficult to say what the character is meant to depict. In some other places, it seems somewhat to resemble a kind of head dress.

116. The bullock and the arm, which generally occur at the beginning of the inscriptions on the obelisks, agree [illegible] well with the epithet MIGHTY in the translation of Hermapion. The arm is, in many other instances, used in compound characters

117. VICTORY is denoted by a branch, perhaps a palm branch, with a semicircle and a circle, sometimes preceded by the waved line.

118. The character signifying FORTUNE somewhat resembles that which denotes "gold" (n. 105), but, instead of the arch, we have an angular line, which seems to be intended for a pair of arms grasping the vase. The whole assemblage approaches, also, a little to the form of a pocket, or purse, as it is frequently delineated.

119. The open square, bent inwards, clearly means SPLENDOUR or glory, though it is uncertain what object it is intended to represent. In some cases, a crescent seems to be substituted for it, as if it bore some relation to the sun, and the moon afforded a parallel sense.

120, 121. ILLUSTRIOUS is expressed, in the inscription of Rosetta, by the open square, for "splendour," the oval, which signifies addition, or respect, making it a kind of superlative, and the pair of legs, which very probably convey the idea of BEARING, or possessing, so that the whole makes the epithet [illegible]. This assemblage is, in some of the manuscripts, very commonly followed by a bird, or its equivalent, a half arch, apparently serving as an intensitive.

[illegible]. 124. The feather, when alone, seems to imply HONOUR, as well as when accompanied by a man stretching out his arm, or by a bird. The bird also, frequently stands alone in similar passages, and must be translated respect, or RESPECTABLE. The block with the bird has also manifestly the same sense in the great ritual, and the vase with the liquid is so nearly synonymous with it, that we can only translate it VENERABLE; and these characters are frequently exchanged for a sort of bench, with a dash under it, a symbol which may, however, possibly have been deduced from some different origin. The sense of the feather is peculiarly illustrated by its occurrence with a drop or club, a serpent, and a line, at the beginning of a great variety of inscriptions, apparently signifying *immortal honour to*. See n. 172.

125. The eye, either with or without the pupil, and either preceded or followed by the undulated line, has a sense somewhat similar to all these, and is often employed at the beginning of the honorary inscriptions. On the Rosetta stone, it means distinctly RITE, or adoration. The enchorial character, corresponding to it, expresses also simply *doing*; as in Greek the same word signifies to "do" and to "sacrifice."

126. WORSHIP, or the Greek ΘΕΡΑΠΕΙΑ, is denoted by a very unintelligible character, resembling a kind of capstan, which is frequently delineated in the boats of the tablets; if it is not intended for some emblematical figure erected in the boats. On the great green sarcophagus, the long bent line is a snake, and the point projecting upwards from the middle is a sword. But these resemblances afford us little or no assistance in tracing the connexion between the whole emblem and its sense.

127, 128. The character denoting [illegible]HER is found in some of the inscriptions of the [illegible], in such circumstances that it might as [illegible] supposed to mean mother; but, by means of Mr [illegible] scarabæus, compared with some other monuments, another character having been determined for MOTHER, it became easy to identify the symbol for father on the Rosetta stone, where it had been a little injured, and imperfectly copied in the engravings.

129. The frequent occurrence of the Egyptian goose, or sheldrake, with a circle over it, between two proper names, sufficiently points out the meaning of these characters, which can only relate to the connexion between them, and which must naturally mean SON; the circle may perhaps be intended for an egg; but in the painted sculptures the disc is red, and the circumference light. The enchorial character nearly resembles the form in which some kinds of birds are usually expressed in the manuscripts (n. 22, 130). Mr Bailey has also observed the occurrence of the bird between two proper names, and has identified it with the CHENALOPEX mentioned by Horapollo, as employed to signify son, on account of its courage in defending its offspring. This quality might rather have been expected to lead to its adoption as a symbol for a parent; but its existence in the bird in question is confirmed by the observations of modern naturalists respecting the sheldrake, the *tadorne* of Buffon, which has generally been considered as the chenalopex, and resembles very accurately the best of the hieroglyphic delineations of the bird, although the colours, as exhibited in the *Description de l'Egypte*, are not correctly natural.

130. The same bird, with a leg or a dash instead of a circle, seems to mean a minister or ATTENDANT, especially in several parts of the inscriptions on the Lover's Fountain. There are also some other characters which seem to be nearly synonymous with these; one of them may possibly be meant for a *tail*, implying a follower, as SAT and SA are nearly alike in Coptic; another is sometimes worn as a collar, perhaps implying subjection, and meaning servant.

131, 132. Instead of the usual character for son, we sometimes find, between two names, a serpent, with a globe substituted for the bird, and an oval for the circle; and the context seems to require that the meaning of these symbols should be a DAUGHTER, but probably with some particular character of royalty or divinity; and at Philae we find a dual, meaning SONS or descendants, as a son and a daughter, expressed apparently by two circles only.

133. A CHILD, or *infant*, is represented by a figure bent as if sitting, and putting his finger on his lip. This is sufficiently established by the triple inscription; but it is still farther confirmed by a plate of the *Description de l'Egypte* (Antiq. II. pl. [illegible]); in which a figure of this kind is represented as immediately derived from the father, who seems to be inspired by a beetle entering his mouth. The manuscripts afford us here some valuable steps, by which the enchorial character is connected with the distinct hieroglyphics. Another figure, which is elsewhere used as corresponding to a beetle, is also found in the enchorial text in the sense of son or offspring.

134, 135. A circle, with an arm holding an angular line, means a DIRECTOR; the angular line is intended for part of a rudder; and the same character, with the addition of the figure of a boat, denotes the pilot or HELMSMAN, as is obvious from many parts of the green sarcophagus. The circle and arm are also found in the character denoting *dedicate*. (N. 150.)

136. A pair of arms holding an oar, and connected by a sort of sector, signifies a ROWER; and possibly also a labourer, or workman in general, as in *image*. (N. [illegible])

137. A stem of a plant, perhaps a reed, followed by an insect like a wasp or ichneumon, but probably intended for a bee, and by two semicircles, is the complete emblem for a KING; but the reed is often used alone in the same sense, and the insect sometimes occurs without the reed. Plutarch says, that a king was denoted by a leaf, THRION; and Horapollo tells us, that a bee signified a people obedient to a king; hence this symbol might be interpreted *king of men*. Ammianus Marcellinus, however, asserts, more simply, that a king was denoted by a bee. It appears from the manuscripts, that the beginning of the enchorial character, which Mr [illegible] reads [illegible], is derived from the [illegible] representing [illegible] and a [illegible] the [illegible] assemblage which [illegible] on the great sarcophagus, and elsewhere, is applied to a royal person. The remainder of the enchorial character seems to repre-

Hieroglyphic Vocabulary

sent a termination consisting of a semicircle and a vessel, which is often added to a name, apparently as a demonstration of respect, like the vessel and the spiral in the case of the god Nilus. (N. [illegible])

138. CONDITION, or subjection, is denoted by a character which somewhat resembles an altar with an offering of flowers; but which might also be intended for the cup of a flower, with an insect hovering over it.

139. In the term SOVEREIGN, the crown is figuratively employed for its wearer; a metaphor common in many modern languages.

140. The character denoting a LIBATION is very indistinctly traced in the sacred inscription of Rosetta, so that it would have been impossible to explain its original form without the assistance of other hieroglyphical monuments. The long water jar, out of which the kneeling figure is pouring a divided stream, somewhat resembles those which a modern Egyptian woman is seen carrying, in a plate of Mr Legh's second edition.

141, 142. The vase with the stream, which frequently occurs in the character for PRIEST, is sometimes found alone, and must therefore probably relate to some particular CEREMONY performed by the priests, approaching to the nature of a libation. On the stone of Rosetta, the line is a simple curve, not waved; nor is the vase more distinctly represented. Instead of the sitting figure, a foot is sometimes substituted, as in the word *attendant* (n. 130): and the enchorial character is a more tolerable approximation to this form than to the complete figure.

143. PRIESTHOOD is simply the *condition* of a *priest*; the character prefixed answering to the Coptic prefix MET, and to the Greek termination EIA.

144. The ornaments of the head are very generally used as indicating the person by whom they are worn; and flowers, probably those of the lotus, are frequently found on the heads of the priests, as well as in the inscriptions which accompany them. In the inscription of Rosetta, the sense SACERDOTAL agrees very well with the context, where this character occurs; though it cannot be deduced with absolute certainty from the comparison with the Greek.

145. It is by no means easy to explain why the figure like a buckle should clearly mean an ASSEMBLY: perhaps, however, the upper part may originally have been a crescent, implying monthly; and the scale or basin below is occasionally found supporting some offerings, which are set upright in it; so that the whole may have meant *a monthly celebration.*

146. The character *god* is made an adjective by the addition of the waved line, and of the long drop, which seem simply to convert it into the term SACRED; unless these have any other meaning, it can only relate to [illegible] or honouring; as the character prefixed in the enchorial text, which is equivalent to the [illegible], is [illegible] to signify [illegible]. In [illegible], a circle and a waved line seem to be employed in a similar manner, for connecting one character with another like substantive and adjective.

147. An epithet, implying CONSECRATED, or dedicated, is composed of a trident, or triple branch or root, followed by a bent line. It occurs very commonly near the beginning of inscriptions, on obeliscs, and elsewhere.

148. A little oblique cross, over an arm with a feather, seems to mean to GIVE, and perhaps to fight and to defend; as, in Coptic, the word TI has both these senses. It is often preceded by a circle and a semicircle.

149. The hand bearing the triangle or pyramid (n. 111) manifestly means, in the frize of Montagu and Ficoroni, to OFFER, as an oblation to a deity.

150. In the inscription of Rosetta, we find the word DEDICATE expressed by a bent line and a sitting figure, with the circle and the arm holding the rudder, n. 134; the character already interpreted *consecrated* precedes, but it is not absolutely certain that it belongs to the same phrase.

151. The term LAWFUL is naturally enough derived from a deity in his judicial capacity; the figure is preceded by a bird, placed between two semicircles, which must here mean *according to*, answering to the termination *ful*. Sometimes a curved line, supported by a stem, is substituted as a synonym for the figure of the judge.

152..154. The character representing GOOD strongly resembles the figure of a lute, depicted in the chamber of the harps, among the catacombs, and may have alluded to the pleasing sound of music. The plural, with the scale or basin, which implies BESTOWING, makes the epithet EUCHARISTUS, which in Greek is somewhat ambiguous, meaning either grateful or MUNIFICENT; the latter, however, must be its sense in [illegible] inscription, because *good gifts* or *delights* may [illegible], but *gratitude* not so easily. The lute is [illegible] denoting good in other parts of the inscription. The enchorial character for the scale could scarcely have been suspected to be derived from it, without the assistance of the manuscripts, which constantly exhibit an intermediate form, intended, perhaps, to comprehend one of the lines supporting the scale.

155. The semicircle, with two oblique dashes, seems to mean GREAT in the name of Thoth, who is called, in the Greek inscription of Rosetta, Hermes the *great and great*: while, in other places, this character seems almost always to convey the sense of a dual. The enchorial epithet of Thoth is a little like the crown with two semicircles, which is most frequently found among the titles of Osiris, especially when he sits in judgment.

155*. The two kinds of hats, worn by the different deities, seem to be intended by the characters of the Rosetta stone, which express the UPPER and LOWER regions or countries. These two characters are also found together in the green sarcophagus as the names of two [illegible]esses; and they occur together in [illegible] passages of some of the manuscripts, and in an inscription at Philae, so that, although the representation is very indistinct in the particular [illegible] of the Rosetta stone, there is little doubt [illegible] of Osiris meant, in this case, *superior*, and that of Hyperion and other personages *inferior*. (Pl. LXXVIII. L.)

156. A circle and a semicircle stand, in several passages of the inscription of Rosetta, for OTHERS, or remaining.

157. Possibly, the bowl and the bird together mean *say* or *call*, and the figure of a man may serve to make the passive CALLED.

158. The second bowl, substituted for the bird, does not appear very essentially to alter the sense, which is still a thing *said* or proclaimed; a DECLARATION, or a decree.

159. The characters denoting MANIFEST seem to have some analogy to *called*, though their derivation is obscure. The first character may either be intended for the country (n. 84), or for a kind of flag or banner.

160. The ring, which implies a NAME, and which, elsewhere, distinguishes proper names, seems to be an imitation of the label, called a "phylactery" in the Greek inscription of Rosetta, on which the name of a figure was usually distinguished.

161. A disc, with rays descending from it, is one of the few characters in which the form gives us some assistance towards determining the sense, which is found to be ENLIGHTENING; though the Egyptians do not seem to have been very correct in their delineation of the motion of light, which they make to diverge in curved lines, like those described by a common projectile. See n. 8, n. 68.

162. The square block, the semicircle, and the chain, are employed very clearly in the sense of LOVING or beloved; the Coptic MAI In the enchorial character the square and semicircle seem to be sometimes transposed, and sometimes changed into an oval.

163. PRESERVER, or saviour, [illegible]esented by a sort of trefoil, with a long stem, [illegible] answers to a cross or obelisc in the enchorial [illegible], in other passages, the character takes the form of a still simpler club: and, in others again, it has something like a bulbous root.

164, 165. (Pl. LXXVII.) A frame like a ladder, supported by a stem, occurs sometimes as a part of a head dress, but it is difficult to say if it represents any other object. Followed by an arm, and a pair of legs, it signifies SET UP, and this combination of characters is of very frequent occurrence; sometimes also the bent line or divided shaft forms a part of it. In Coptic, *set up* is expressed by *set on foot*, which seems to retain the analogy of the hieroglyphical character. The substitution of a pair of feathers for the legs, however, does not appear materially to alter the sense; the context, where it occurs, requiring the word PREPARE or construct.

G. RELATIONS.

166. Two ovals, with a semicircle and an arm, very clearly signify IN ORDER THAT. The ovals seem to mean to or *for*, and the arm action or *doing*; as our own *that* seems to be allied to the German *that*, which means *deed*. The same combination of characters appears to denote, in another passage, *to add to*; and one of the ovals is sometimes omitted. The Coptic may be either HINA or ETHBE.

167. The symbols, employed in the sense WHEREVER, seem to mean separately, *at*, *in*, *one*, or *in*, *place*, *one*; and transposing the two last, we may make a very good Coptic word [illegible]-O-MA.

168, 169. The arm and chain signify AND or ALSO; and the oval sometimes takes place of the arm, without much variation of the sense; this combination is also found in the sense of *with*, or *together with*. The elementary ideas seem to be *put*, *with*, or *add*, *with*. Between the names of Ptolemy and Berenice at Karnak, the arm and chain are separate.

170. The half arch, or the fork, which is perfectly equivalent to it, followed by two curls and two semicircles, mean MOREOVER: the reduplication probably resembling that of many of the Coptic verbs, which generally imply a continued action.

171. The combination of the loop or sling, with two semicircles and three ovals, means very clearly LIKEWISE. The loop seems to represent a bucket, intended for one of a pair, to be carried on a pole, as they are frequently delineated in the tablets; so that it must mean a *companion*; and accordingly we find it in a very common epithet of a king, on obelisks and elsewhere, with a circle and a [illegible], denoting *the companion of the sun*, or simply *resembling the sun*. In the enchorial character for *likewise*, the symbols seem to be transposed, and the loop is doubled.

172. An owl, signifying IN, seems to be nearly synonymous with the half arch, which is also sometimes to be understood in the sense of *all*: both these characters occur also in many instances where they can only be considered as marks of respect, and not very essential to the sense; and in this they resemble the Coptic prefix M, which is a particle not very distinctly intelligible, nor capable of being translated; it is also not a little remarkable, that the M of Akerblad's alphabet is the enchorial character which answers to [illegible] these symbols. (See n. 128.)

173, 174. A [illegible] over two waved lines is employed, either alone, or together with a head, dash, circle, and dash, which have separately a similar sense, for UPON, OVER, or *at*; and it is remarkable, that a similar relation exists in Coptic between [illegible], and EJO; JO or [illegible] also meaning a head. The enchorial character, in some of its forms, is manifestly a coarse imitation of an animal. The head is always represented in the manuscripts, by a character nearly like a Greek Σ; and this may possibly have been the origin of the Coptic letter JANJIA, if it was derived from a hieroglyphic; but it is equally probable that it may have been intended for a combination of a delta and a *chi*.

175. A semicircle and an oval mean FOR, as relating to time.

176. A ball, with two short appendages, one narrower than the other, occurs several times on the Rosetta stone, and seems to have been intended for a head seen in profile, which is often found on other monuments. This character, together with a dash, seems [illegible] year, or *each*; [illegible] *every* year, or [illegible].

177. The hat, interposed between "an image" and "the king," can only mean OF, or FOR; it is often

substituted, in passages which are frequently repeated, for the waved line; each being probably equivalent to the Coptic NTE, or rather N, which sometimes makes an adjective of a substantive, as NNUB, golden, from NUB, gold. See [illegible] 140.

H. TIME.

178. A DAY seems to be very naturally expressed by *splendour of the sun*, or *sunshine*. See n. 119, n. 8.

179. A crescent turned downwards, with a star and the sun, makes up the character signifying a MONTH; to which a semicircle and a scale or basin are sometimes added. Horapollo says, that a month is denoted by a palm branch, or by an inverted crescent; but the crescent is too indistinct, on the stone of Rosetta, to have allowed us to recognise it, without the assistance of the collateral inscriptions.

180. A YEAR is denoted by a bent line with a little projection from the middle, which seems to represent a plant with an annual shoot or bud; it is commonly followed by a semicircle and a block or dash.

181. There is some little uncertainty respecting the exact limits of the characters denoting the first month THOYTH. The name seems to have some relation to gathering the harvest, and the emblem is probably intended for a field of corn; and, perhaps, as the year is said to have begun originally with the dogdays, the appropriation of this character to the first month may have been connected with the origin of the calendar.

182, 183. The sixth month, MECHIR, is remarkable for having half as many crescents as the twelfth MESORE: this relation would, without doubt, be further illustrated, if we could discover any thing like a calendar, among the immense mass of Egyptian literature, which is still in existence: the manuscript, which Montfaucon calls a calendar, merely because it is divided into twelve columns, has no pretensions to the name.

184, 185. The symbol for the sun seems to be employed in the designation both of the FIRST DAY of the month, the NEOMENIA of the Greek inscription, and of the last, or THIRTIETH DAY. Of the characters following the sun, the one seems to mean *good*, or rather *new*, as in Thoyth, the month of the new year: the other *old* or *last*. This character might be taken for a serpent, or for a branch of a tree; but it seems more probable that it is intended for the *tail* of an animal, since it occurs in several passages of the manuscripts as representing a tail; and the tail of the month is sufficiently expressive of the [illegible]. See n. 130.

I. NUMBERS.

186. UNITS are denoted by short lines, like the Roman I. [illegible] numerals in the [illegible] of Rosetta, where the Greek [illegible] words "first and second" only remain; and this observation alone was sufficient to prove, that the hieroglyphical characters related to a real language, and were not simply ornamental decorations, as some persons have imagined.

187 . . 196. The twisted line, distinguishing the ORDINAL NUMBERS, answers to the Coptic MAH; which is prefixed to the cardinals in the same sense; in the enchorial text the corresponding character follows the number. The THREE points are more commonly employed, when they follow a word, to make it plural; but when they signify a numeral, they are generally placed immediately above some other character; and, in the enchorial inscription, this numeral is distinguished by making the lines oblique and joining them.

197. For the number TEN we have a Greek *pi*, either square or rounded, not only in the inscription of Rosetta, but in many other places.

198. We find the number SEVENTEEN recurring twice as a date in the inscription of Rosetta; the Greek text, in another part, alluding to the same period, has 18; and the enchorial words are too indistinctly marked to allow us to judge of the identity or diversity of the two numbers; but the difference of a day is of no consequence, since the festival of the "assumption of the kingdom" may easily have begun on the 17th of Mechir, and have continued to the next day, which is the date of the decree.

199, 200. The enchorial character for THIRTY, applied to years, seems to be the same as is elsewhere used in the sense of the *thirtieth day*; but the numbers are almost always confused in the running hand, and exhibit several deviations from the regular system of the sacred characters; the number FORTY, for example, in the remarkable passage relating to the [illegible] of Osiris, seems to be denoted by a [illegible] with a dash on it.

201. [illegible], like the figure 9, meaning A HUNDRED, and the hatched circle, supported by a cross, denoting A THOUSAND, occur in several inscriptions, so combined with units and tens, as to leave no doubt respecting the numbers that they represent. This is particularly evident from the consideration of an inscription "believed to have been found at Karnak." (*Descr. de l'Egypte. Ant.* III. Pl. 38. F, 26 . . 30.)

204. PLURALS are distinguished by writing a character three times, or by putting three dashes after it; and sometimes, perhaps, though very rarely, before it: occasionally also by repeating a part of a collection of symbols once only. In the manuscripts, the three dashes are generally joined into a crooked stroke; which, in the enchorial inscription, sometimes both precedes and follows the word; while, in other cases, the second stroke is converted into a single vertical line, which serves to limit the extent of the character meant to be made plural; the [illegible] being so imperfect, that this assistance is more required than in the sacred characters: and it may be observed, that this second mark is never wanting in the enchorial inscription, as it [illegible] have been, if the character had been [illegible]; since many of the Egyptian plurals end exactly as their singulars do; and even when they differ from them, it is not by the addition of any one uniform termination.

K. SOUNDS.

205 . . 218. The *phonetic characters*, according to the traces which may be discovered in the words Berenice, Ptolemy, Greek, and some others (n. 56, 58, 74, 83, 128, 172), will afford something like a hieroglyphic alphabet, which, however, is merely collected as a specimen of the mode of expressing sounds in some particular cases, and not as having been universally employed where sounds were required. The *supposed enchorial alphabet*, which is subjoined, is applicable to most of the proper names in the inscription of Rosetta, and probably also to some other symbols which have been the prototypes of the characters: it is taken from the alphabet of Akerblad, but considerably modified by the conjectures which have been published in the *Museum Criticum*.

L. ADDITIONS. Pl. LXXVIII. See n. 21, 78, 155.

M. SPECIMENS OF PHRASES.

The last line of the inscription of Rosetta will serve as a specimen of the way in which the hieroglyphical characters were combined, so as to form a language; and will show at the same time the relation between the sacred and the enchorial texts. At the beginning of the line we find some obscurity, and a want of perfect correspondence in the two inscriptions; but it is clear that the fork or ladder, the arm and the feathers, mean to *prepare* or procure (n. 165); then follows *a column* (n. 91); the wavy line, *of* (n. 177); the semicircle and two dashes, with the arm, probably [illegible]; the [illegible] square below, with its [illegible] the [illegible] or knot, *wrought* or engraved [illegible]; the instrument or case, *writing*, or letters (n. 108); the wavy line, the hatchet, and drop, with the three dashes making a plural, *appropriate to the gods*, that is, sacred (n. 146); the case again, *letters*; the hat, *of* (n. 177); the ladder, arm, and feathers, *the country*; the serpent and bent line, approaching to the sense of perpetuity and greatness, seem to be a mark of respect to the country, though it is barely possible that they may be substituted for the repetition of the instrument or case, and may mean the language, and belong to the following curl on the stem, the feathers, the serpent, and the hat, which signify *Greek* (n. 83). The headdress of flowers meaning probably *a priest*, the following oval with the dashes probably ornamental or honorary, or perhaps collective, and the two bowls, with the man [illegible] the plural, a publication (n. 158), the whole of these symbols must express *the honorary decree of the priests, or the decree of the assembled priesthood*; but the enchorial text seems to [illegible] the symbol for honour. The oval, with the semicircle and arm, implies in order that, *in order to*; the fork with cross bars, the arm, the legs, and the spike, *set it up* (n. 164); the bird, *in* (n. 175); the three broad feathers over as many open squares, *the temples*, and [illegible] plural; the half arch and oval with the plural dashes, all, or *of all kinds*; the open square, wheel, scale, head, dash, and ring, Egypt (n. 80); the figure with a vase on his head, subjection or power, as in n. 129, making the whole belonging to Egypt, or *throughout Egypt*; the fork and dash are in, or *in all*; the [illegible], followed by the numbers, *of the first, the second, and the third order* (n. 187, 189, 191): the oval, half arch, and dash, *wherever*, or in which, leaving out "shall be;" the tool and standing figure, with the intervening characters, *the image* (n. 101); the hat, *of*; the reed and bee, with the semicircles, *King*; the square, semicircle, lion, half arch, two feathers, and bent line, *Ptolemy* (n. 56); the handled cross and serpent with the two semicircles, *the everliving* (n. 110); the square block, semicircle, and chain, *dear to* (n. 162); the hieralpha and two feathers, *Phthah*, or Vulcan (n. 6); all this being included within the ring or phylactery together with the name; the open square, the oval, and the pair of legs after the ring, *illustrious* or Epiphanes (n. 161); and lastly, the scale, and the three lutes, *magnificent* (n. 154); the conjunctions being often omitted, as they also very commonly are in Coptic, and even in Greek.

The enchorial text agrees in many places extremely well with the hieroglyphics, according to the general style of imitation which has been already explained and exemplified, although in some passages there is a greater difference than might have been expected. The beginning of the enchorial seems to contain the word decree, which cannot be found in this part of the hieroglyphics; the character for letters occurs three times in it, as if the second character used in the third place meant language; "sacred [illegible] decree" of the sacred characters is omitted in the corresponding part of the enchorial; the word temples is repeated before each numeral; the [illegible] wherever is amplified; the image is a very [illegible], and is followed by the character for a deity, meaning sacred or divine; and, lastly, the name of Ptolemy is omitted, the word king being only followed by " whose life shall be for ever;" or a phrase of similar import.

N. COMPARISON OF MANUSCRIPTS.

The subjoined specimens of a comparison of the different manuscripts, which deviate more or less from the form of distinct hieroglyphics, with others in which those characters are preserved almost entire, though slightly traced, will serve to show the complete identity of the different systems in their original form; the first and fourth lines being taken from the great hieratic manuscript of Strasburg, and the rest from other copies of the same text, which are universally considered as written in the epistolographic character. We cannot discover the entire connected sense of the whole passages, but we may easily observe the symbols for gods, [illegible] Osiris, [illegible] Nephthe, "Hieracion," to [illegible] child or priest. (Descr. de [illegible] LXXV. [illegible] col. 3; [illegible] LXXII. [illegible] LXVII. col. 2.)

SECTION VIII.—*General Character and Subjects of the Egyptian Monuments.*

By means of the knowledge of the hieroglyphic characters, which has been already obtained, we are fully competent to form a general idea of the nature of the inscriptions on the principal Egyptian monuments that are extant. Numerous as they are, there is scarcely one of them which we are not able to refer to the class either of sepulchral or of votive inscriptions; astronomical and chronological there seem to be none, since the numerical characters, which have been perfectly ascertained, have not yet been found to occur in such a form as they necessarily must have assumed in the records of this description: of historical nature, we can only find the triumphal, which are often sufficiently distinguishable, but they may also always be referred to the votive; since whoever related his own exploits thought it wisest to attribute the glory of them to some deity, and whoever recorded those of another, was generally disposed to intermix divine honours with his panegyric. It has, indeed, been asserted, that the Egyptians were not in the habit of deifying any mortal persons; but the inscription of Rosetta is by no means the only one in which the sovereigns of Egypt are inserted in the number of its deities; the custom is observable in monuments of a much earlier age; indeed, in such a country it might be considered as a kind of dilemma of degradation, whether it was most ridiculous to be made a divinity, or to be excluded from so plebeian an assemblage; but flattery is more prone to err by commission than by omission, and, consequently, we find the terms king and god very generally inseparable. The sepulchral inscriptions, from the attention that was paid in Egypt to the obsequies of the dead, appear, on the whole, to constitute the most considerable part of the Egyptian literature which remains, and they afford us, upon a comparative examination, some very remarkable peculiarities. The general tenor of all these inscriptions appears to be, as might be expected from the testimony of Herodotus, the identification of the deceased with the God Osiris, and probably, if a female, with Isis; and the subject of the most usual representations seems to be the reception of this new personage by the principal deities, to whom he now stands in a relation expressed in the respective inscriptions; the honour of an apotheosis, reserved by the ancient Romans for emperors, and by the modern for saints, having been apparently extended by the old Egyptians to private individuals of all descriptions. It required an extensive comparison of these inscriptions to recognise their precise nature, since they seldom contain a name surrounded by a ring in its usual form; sometimes, however, as on the green sarcophagus of the British Museum, a distinct name is very often repeated, and preceded by that of Osiris; while, in most other instances, there is a certain combination of characters, bearing evident relation to the personage delineated, which occurs after the symbols of Osiris, instead of the name; so that either the ring was simply omitted on this occasion, or a new, and perhaps a mysterious name was employed, consisting frequently of the appellations of several distinct deities, and probably analogous to the real name. That the characteristic phrase, so repeated, must have had some relation to the deceased, is proved by its scarcely ever being alike, in any two monuments that have been compared, while almost every other part of the manuscripts and inscriptions are the same in many different instances, and some of them in almost all; and this same phrase may be observed in Lord Mountnorris's and Mr Bankes's manuscripts, placed over the head of the person who is brought up between the two goddesses, to make his appearance before the true Osiris, in his own person, and in his judicial capacity, with his counsellors about him, and the balance of justice before him. (Hierogl. 5. E F G e f.) In this instance the phrase consists of the names of "Hyperion" and the Sun, preceded by a block and an arm with an offering (Plate LXVIII. O), and it may be interpreted, without any violence, "the votary of Hyperion, and of Phre." In a small manuscript, engraved by Denon, the part which resembles the characteristic phrase of other manuscripts, is followed by the name of a king (P), which is nearly identical with that of the father of the Pseudomemnon in the British Museum (Q), the one having the hieralpha laid flat, the other the traces of the pedestal, which is equivalent to it. (N. 6.)

The tablet of the last judgment, which is so well illustrated by the testimony of Diodorus concerning the funerals of the Egyptians (Sect. 5.) is found near the end of almost all the manuscripts upon papyrus, that are so frequently discovered in the coffins of the mummies, and among others in Lord Mountnorris's hieratic manuscript, printed in the Collection of the Egyptian Society. The great deity sits on the left, holding the hook and the whip or fan; his name and titles are generally placed over him; but this part of the present manuscript is a little injured. Before him is a kind of mace, supporting something like the skin of a leopard; then a female Cerberus, and on a shelf over her head, the tetrad of termini, which have been already distinguished by the names "Tetrarcha," Anubis, Macedo, and "Hieracion," each having had his appropriate denomination written over his head. Behind the Cerberus stands Thoth, with his style and tablet, having just begun to write. Over his head, in two columns, we find his name and titles, including his designation as a scribe. The balance follows, with a little baboon as a kind of genius, sitting on it. Under the beam stand "Cteristes" and "Hyperion," who are employed in adjusting the equipoise; but their names in this manuscript are omitted. The five columns over the balance are only remarkable as containing, in this instance, the characteristic phrase, or the name of the deceased, intermixed with other characters. Beyond the balance stands a female, holding the sceptre of Isis, who seems to be called Rhea, the wife of the sun. She is looking back at the personage who holds up his hand as a mark of respect, and who is identified as the deceased by the name simply placed over him, without any exordium. He is followed by a second goddess, who is also holding up her hands, in token of respect; and whose name looks like a personification of honour or glory, unless it is simply intended to signify "a divine priestess" belonging to the order of the Pterophori mentioned on the Rosetta stone. The forty two assessors are wanting in this tablet; and, in many other manuscripts, their number is curtailed, to make room for other subjects; but, in several of those which are engraved in the *Déscription de l'Egypte*, they are all represented, sometimes as sitting figures, and sometimes standing as termini, with their feet united.

The principal part of the text of all these manuscripts appears to consist of a collection of hymns, or rather homages to certain deities, generally expressed in the name of the deceased, with his title of Osiris, although the true Osiris is not excluded from the groups that are introduced. The upper part of each manuscript is occupied by a series of pictural tablets; under them are vertical columns of distinct hieroglyphics, or, in the epistolographic manuscripts, pages of the text, which are commonly divided into paragraphs, with a tablet at the head of each, the first words being constantly written with red ink, made of a kind of ochre, as the black is of a carbonaceous substance. The beginning of the manuscript is seldom entire, being always at the outside of the roll; as the "umbilicus" of the Romans was synonymous with the end. Not far from the beginning, we always find a large tablet, occupying the whole depth of the paper, representing the sun adored by his ministering spirits. In the large hieratic manuscript, which occupies four plates of the *Déscription de l'Egypte,* and which may be considered as a fine specimen of the most highly finished copies, there are at present only four columns remaining before this tablet. It is followed by a short section, with a rubric, which is not very distinctly expressed; after this are 35 others, beginning with a long rubric (Plate LXXVIII. R.), which is usually followed by the name of a divinity, represented in a neighbouring part of the margin, and which may be supposed to mean something like "Respect and reverence be paid to each of the sacred powers." The next ten sections begin with the rubric of a feather, and a sitting figure raising his hand to his head, as if holding a vase on it (S), meaning probably "Honour is due," or belonging to; then follow the name and titles of Thoth or Hermes, and the phrase describing the deceased in the character of Osiris; and afterwards, the names of each of a group of deities, which is represented in the corresponding tablet with an altar and a suppliant before them. These groups are different in the different sections, but they correspond pretty accurately with each other in the various manuscripts, and this hermetic decad is the most constant part of the manuscripts found with the mummies, though a little more extended in some than in others. (Hierogl. 4.) After these, we find 35 sections, beginning with a drop, a feather, a serpent, and a line (T); the rubric being immediately followed by the deified name peculiar to the manuscript. This exordium, from the analogy of the term sacred (n. 146), we can have no hesitation in understanding as a derivative of the feather, signifying honour or ornament, and the serpent signifying perpetuity, and in translating it, "Eternal honour" or respect. A similar sense seems, in other places, to be expressed by the open square or the pyramid, instead of the feather (U, V); and not uncommonly the hat is substituted for the line, without any variation of the meaning (W). After these 35 sections, we have two others, of which the rubrics are less intelligible, followed by 42 short ones, which evidently contain the names and titles of as many separate deities, whose figures are commonly represented in the great tablet, near that of Osiris. We may generally observe, among the epithets of each, the term "illustrious" (n. 121); and each section has a second paragraph, beginning with a pair of arms extended, a character which seems occasionally to be used in reference to the equal scales of justice, though on the stone of Rosetta it appears to signify a kind of temple, so that it may possibly relate to the honours to be paid to these divine judges. With a few additional columns, and with the great tablet of the judgment, the manuscript concludes. It does not contain the figure of the sacred cow, which is the termination of most other manuscripts; nor the agricultural representations, which are frequently found in many of them, especially in that of Lord Mountnorris (Hierogl. 3), with the three deities sitting in a grotto under it. The last of these, according to the inscriptions over the two boats, is meant for Arueris, the second apparently for the mother of the sun, and the first for Osiris; and one of the boats carries the steps, which seem to be emblematic of the solar power; the other the throne or chair of state, which is universally appropriated to Osiris.

The coffins of the mummies, and the large sarcophagi of stone, are generally covered with representations extremely similar to some of those which are found in the manuscripts. The judicial tablet is frequently delineated on the middle of the coffins; above it are Isis and Nephthe, at the sides; and apparently Rhea in the middle, with outspread wings. The space below is chiefly occupied by figures of twenty or thirty of the principal deities, to whom the deceased, in his mystical character, is doing homage; each of them being probably designated by the relationship in which he stands to the new representative of Osiris. In the sculptures, the figures are generally less numerous; the same deities are commonly represented as on the painted coffins, but without the repetition of the suppliant, and in an order subject to some little variation. The large sarcophagus of granite, in the British Museum, brought from Cairo, and formerly called the Lover's Fountain, has the name of Apis, as a part of the characteristic denomination. This circumstance, at first sight, seemed to make it evident that it must have been intended to contain the mummy of an Apis, for which its magnitude renders it well calculated; but, when the symbols of other deities were found in the mystic names upon various other monuments, this inference could no longer be considered as absolutely conclusive.

Of the votive or dedicatory inscriptions we find an interesting example on a small scale, in the engraving on the bottom of a scarabæus, very neatly sculptured in a softish steatite, or lapis ollaris, brought from Egypt by Mr Legh, and now in the possession of Dr Macmichael. (Plate LXXVIII. X.) It is remarkable for its simplicity, and for affording an intelligible sense in all its parts. The chain, the semicircle, and the square block, mean clearly [*To*] *the beloved;* the loop supporting a wreath or crown, and the imperfect sitting figure, resemble some of the titles often given to Osiris, and with the following oval pretty certainly signify *of the great god;* the throne, the semicircle, and the oval, *Isis;* the sitting figure, *the goddess;* the looped wreath, perhaps *the great;* the bird and circle, *offspring of;* the hieralpha or lough, and the two feathers, *Phthah;* the pillar perhaps *the powerful*, but it is not distinctly formed; the beetle seems to be here a synonym or epithet of Phthah, as if *the father of all;* the handled cross, *the living;* the lute, *the good;* the pyramid, *the prosperous* or glorious: the ring with the handle seems to be nearly synonymous with the chain, and may be rendered, in conjunction with the line and the hieralpha, *the approved of Phthah*, an epithet found in the inscription of Rosetta; the hatchet is *the deity;* the ring and handle, with the two lutes, approaches near to the symbol for munificent (n. 154), and may be called *delighting in good gifts;* and the concluding ring and staff or hatchet may either mean, this is dedicated; or may, with rather more probability, be considered as a reduplication of the beginning of the line, in an inverted position. It may be remarked, that all the inscriptions on the scarabaei run from right to left, as is most commonly observed wherever the direction was indifferent; so that if they were used as seals, the impression must have assumed the form which is somewhat less usual in other cases.

We have a most valuable example of a dedicatory inscription on a larger scale in the decree preserved on the stone of Rosetta, which, besides its utility in affording the only existing clue for deciphering the hieroglyphic characters, gives us also a very complete idea of the general style of the records of the Egyptian hierarchy. Of the triumphal monuments, the most magnificent are the obeliscs, which are reported by Pliny to have been dedicated to the Sun; and there is every reason to suppose, that the translation of one of these inscriptions, preserved by Ammianus Marcellinus, after Hermapion, contains a true representation of a part of its contents, more especially as "the mighty Apollo" of Hermapion agrees completely with the hawk, the bull, and the arm, which usually occupy the beginning of each inscription. These symbols are generally followed by a number of pompous titles, not always very intimately connected with each other, and among them we often find that of "Lord of the asp-bearing diadems," with some others, immediately preceding the name and parentage of the sovereign, who is the principal subject of the inscription. The obelisc at Heliopolis is without the bull; and the whole inscription may be supposed to have signified something of this kind. "This Apollinean trophy is consecrated to the honour of King "Remesses," crowned with an asp-bearing diadem; it is consecrated to the honour of the son of "Heron," the ornament of his country, beloved by Phthah, living for ever; it is consecrated to the honour of the revered and beneficent deity "Remesses," great in glory, superior to his enemies; by the decree of an assembly, to the powerful and flourishing, whose life shall be without end." It is true, that some parts of this interpretation are in great measure conjectural; but none of it is altogether arbitrary, or unsupported by some probable analogy: and the spirit and tenor of the inscription is probably unimpaired by the alterations, which this approximation to the sense may unavoidably have introduced.

Of the obeliscs still in existence there are perhaps about thirty larger and smaller, which may be considered as genuine. Several others are decidedly spurious, having been chiefly sculptured at Rome in imitation of the Egyptian style, but so negligently and unskilfully, as to have exhibited a striking difference even in the character of the workmanship. Such are the Pamphilian, in explanation of which the laborious Kircher has published a folio volume, and the Barberinian or Veranian: in both of these the emblems are put together in a manner wholly arbitrary; and where an attempt is made to imitate the appearance of a name, the characters are completely different at each repetition. The Sallustian obelisc has also been broken, and joined inaccurately, and some modern restitutions have been very awkwardly introduced, as becomes evident upon comparing with each other the figures of Kircher and of Zoega. Another very celebrated monument, the Isiac table, which has been the subject of much profound discussion, and has given birth to many refined mythological speculations, is equally incapable of supporting a minute examination upon solid grounds; for the inscriptions neither bear any relation to the figures near which they are placed, nor form any connected sense of their own; and the whole is undoubtedly the work of a Roman sculptor, imitating only the general style and the separate delineations of the Egyptian tablets, as indeed some of the most learned and acute of our critical antiquaries had already asserted, notwithstanding the contrary opinions of several foreigners, of the highest reputation for their intimate acquaintance with the works of Greek and Roman art. We may hope, however, that in future these unprofitable discussions and disputes will become less and less frequent, and that our knowledge of the antiquities of Egypt will gain as much in the solidity and sufficiency of its evidence, as it may probably lose in its hypothetical symmetry and its imaginary extent; and while we allow every latitude to legitimate reasoning and cautious conjecture, in the search after historical truth, we must peremptorily exclude from our investigations an attachment to fanciful systems and presupposed analogies on the one hand, and a too implicit deference to traditional authority on the other. (I. J.)

ELBA, an island of the Mediterranean, separated by a narrow channel from the western coast of Italy. It lies in 42° 49′ 6″ N. Lat., and 10° 9′ 24″ E. Long. from London. It is about 70 English miles in circuit, but the coast is very winding and irregular.

Elba is supposed to have been first peopled by a colony of Etruscans, but was afterwards occupied by a body of those Greeks who founded Marseilles. It fell afterwards under the dominion of Carthage, and was taken by the Romans during the first Punic war.

In the second, Elba supplied iron for naval and military purposes, and was considered as one of the states which had saved the republic. In the contest between Sylla and Marius, the adherents of the latter fled thither for refuge, and Elba became thus involved in prescription and devastation, from the effects of which it never recovered under the Roman dominion. In modern times, it became attached to the commercial republic of Pisa, under whose auspices it rose to a comparatively flourishing state. On the annexation of Pisa to Milan, Elba, with Pianosa, Monte Cristo, Piombino, and other territories, was formed into a little principality, which continued for about two centuries in the hands of Gherardo d'Appiano and his successors; though it was repeatedly occupied as a military station by Charles V. and his ally, the Grand Duke of Tuscany. Being thus involved in the wars of that monarch with the Porte and the Barbary states, Elba became exposed to the incursions of the Turkish corsairs It was laid waste with fire and sword, once by Barbarossa, and twice by Dragut, and has never fully recovered from these ravages. Under Philip III. it merged into the possessions of Spain, and that prince ordered the construction of Porto Longone, which proved a barrier against the incursions of the corsairs. Several transferences then took place, the result of which was, that, from 1735, the King of Naples had possession of Porto Longone, and the Grand Duke of Tuscany of Porto Ferraio. Elba continued in this state till the French revolution, when it first became part of the kingdom of Etruria, and was then annexed to France. It afterwards attracted a remarkable degree of attention, by becoming the temporary residence of Napoleon Buonaparte. Upon his second downfall, Elba was ceded to the Grand Duke of Tuscany.

The island of Elba is entirely filled with mountains, which are formed into three distinct clusters, separated by a valley, which widens as it approaches the sea. The highest are those situated on the western part of the island, the pinnacle of which, called Monte Capanna, rises upwards of 3000 feet above the level of the sea. The greater part of these hills present an arid, rugged, and often ruinous aspect; but a few are embellished with myrtles, laurels, wild olives, and other verdant shrubs. This western part is almost entirely composed of granite, which forms also the basis of the soil in this quarter of the island. Rock crystal is found abundantly, and often in large masses, but somewhat injured in its transparency, and when combined with alum and slate, produces numerous varieties of calcedony, particularly that called *cachalong* The eastern mountains are composed of serpentine and schistus, and abound with aluminous mixtures; but they are chiefly distinguished by the iron which they contain.

From the earliest times, Elba has been celebrated for an uncommon iron mine. It is said by Pliny to have been mentioned in the treaty between Porsenna and the Romans, after the expulsion of the kings. Virgil calls it

> "Insula, inexhaustis chalybum generosa metallis."

This mine consists of one entire mountain, about 500 feet high, and bathed by the channel which separates the island from the opposite coast of Piombino. The whole mountain is filled with iron, distributed in confused masses, and in every known variety of form; green and black ore, mica, manganese, hematite, &c. The most rare and remarkable mineral here produced is the crystallised iron. The crystals are of various forms, some lenticular, others specular, with brilliant and polished fronts; others shaped like the comb of a cock, spires, pyramids, &c., while others are polygons and pointed, like diamonds. They have usually the colour and brightness of polished steel, but are sometimes tinted green, red, black, yellow, brown, and violet. A few pieces offer to the enchanted eye the appearance of an assemblage of all the precious stones. The mineralogical cabinet of Florence contains a splendid collection of these specimens, and there are some good ones in the British Museum. The mine of iron extends about a mile into the mountain, and the working was formerly conducted by galleries, but now proceeds under the open sky. The Elbese do not possess the art of forging this iron, which is therefore carried to the founderies of Corsica, and of the opposite coast of Italy. About 18,000 tons are sold, and about 120 vessels, of from 40 to 100 tons each, are employed in exporting it to the neighbouring coasts.

The soil of Elba is unequal, and wants depth; in consequence of which, and of the want of industry in its inhabitants, scarcely any corn is raised. They grow, however, maize, pease, beans, and other species of pulse. Fruits are in general bad; but figs and chesnuts are very plentiful, and the olive and mulberry flourish through the greater part of the island. The most valuable vegetable produce is the grape. The white wine is common, and used only at home; but the red wine is exquisite, though in small quantity; and there are two kinds of dessert wine, both highly esteemed, called *Vermont* and *Aleatico.* Wood, both for fuel and carpenter's work, is very scarce; yet Elba produces two remarkable trees, the American aloe and the Indian fig, both of which attain a greater height here than in other parts of Italy. The tunny fishery is considerable, and is carried on both at Porto Ferraio, and Marciana. The tunnies visit this coast twice in the year, from April to July, and from September to the end of October. The fishery forms a sort of festival; the sea is covered with boats, which form a vast enclosure, into which, when the tunnies have entered, they are pierced with harpoons, and the sea is reddened with their blood. The annual amount is about L 2500 Sterling. Pearl oysters were formerly caught, but this fishery has been exhausted. There are numerous marine marshes from which salt is evaporated, though the manufacture is not well conducted. The produce is 60,000 sacks, of about 150 lbs. each.

The population of Elba was, in 1778, estimated at 8000, but it has since risen to 12,000 souls. They are a race, differing, in many respects, from that which inhabits the continent of Italy. They are well made and robust, and often attain a great age without experiencing ailment or infirmity. They are brave, active, hardy, laborious, and, at the same time, kind-hearted and hospitable. They are, however, irritable and impatient of contradiction. They are almost universally ignorant and credulous, yet have a certain liveliness of imagination, which renders them fond of extravagant and romantic tales. The females are not in general handsome, but to this there are some exceptions; they are generally virtuous, and make good wives and mothers.

The principal town of Elba is Porto Ferraio, which contains a population of 3000 souls. The houses are small and inconvenient, but the streets are wide, and are in general terraces cut in the rock. Vast subterraneous magazines have been here constructed for the preservation of corn and other necessaries, with a view to provisioning the place in case of siege. The inhabitants are said to have lost the simplicity of the rural districts, without attaining any real information or refinement. Porto Longo is a well fortified town, with an agreeable and picturesque neighbourhood, and contains 1500 inhabitants. Rio is poor, and is only supported by the great iron mine, which is situated in its neighbourhood; its population may be 1800 souls. Other villages and districts are Capo Liveri, Campo, and Marciano.—*Voyage to the Island of Elba.* By Arsenne Thiebaut de Berneaud, translated by W. Jordan, 8vo. 1814.—*Tour through the Island of Elba.* By Sir Richard Colt Hoare, Bart. 4to. 1814. (B.)

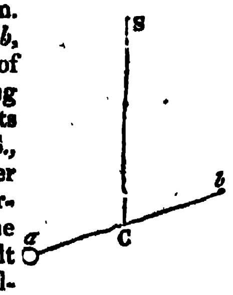
ELECTRICITY.

Most of the *phenomena* which Electricity presents have been described at large in the Encyclopædia; and the *experimental* part of the science remains nearly in the same state as at the publication of that work. This is not the case, however, with the *theoretical*. The theory was then founded on suppositions more or less doubtful; on ingenious but contracted views of the subject; and rather on empirical relations among the phenomena, than on calculations rigorously mathematical. It is to supply this defect, that we must especially devote ourselves in this Supplement, and happily the progress of science affords ample materials.

To proceed methodically in the concentration of the electrical phenomena, let us recal successively all the general laws in which they are recorded, and which are established by experiment. The first consists in the mutual attraction or repulsion which electrified bodies exert, or *seem to exert*, towards each other. These properties are exhibited when we electrify a tube of glass or of resin, by rubbing it on a woollen cloth, and then touch with this tube small and light balls of wood, or the pith of the elder, suspended in a dry state of the air by threads of silk equally well dried. In this case, the silk prevents the escape of the electricity, and the air also possesses the same faculty. The little balls being only in contact with insulating bodies, are thus protected from any waste of their power. They are what we term *insulated*. But the moment the electrical property is *communicated* to them, they mutually fly asunder, and, contrary to the tendency of gravity, recede from the vertical; precisely as if the electricity which attaches itself to their surfaces had determined them to repel each other.

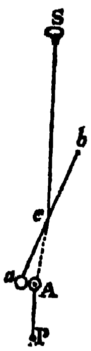
The result is alike, whether the little balls have been touched with the tube of glass, or with that of resin, provided both are touched with the same. But, if one of them be touched with the tube of resin, and the other with the tube of glass, these two tubes having been both rubbed on a rubber of the same nature, then the two balls approach each other, contrary to the tendency of gravity, as if by a mutual attraction. This result being opposite to the first, obliges us to distinguish two modifications of electricity different from each other, at least in the apparent effects which they produce. These are what have been termed *positive and negative electricity*. We shall not employ these terms on account of their already presenting to the mind the ideas of *addition* and *subtraction*, which are really hypothetical, since they go beyond the facts. To express the distinction between the two kinds of electricity, we shall name them according to the method which serves to develope their influence. We shall call that *vitreous electricity* which a tube of glass exhibits when rubbed on a rubber of wool, and that *resinous electricity* which is obtained on rubbing upon the same rubber a tube of resin; though either of these electricities could be yet produced by some other proceeding different from what we have indicated in this definition.

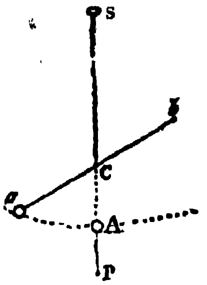
We must now seek, by experiment, for the law according to which these attractions and repulsions operate, that is to say, what their relative intensity may be at different distances. The separation of the little balls furnishes an index of this; but it is not sufficiently delicate, and, as we shall soon see, too complicated, to measure it with exactness. The same may be said of all the contrivances in which weights so small as they must necessarily be, are made to balance the attraction or the repulsion. The *torsion* of metallic wires is the only force sufficiently minute, sufficiently constant, and whose effect can be estimated with sufficient ease, to be employed with advantage in measurements of this kind. Such is the object of the *electrical balance* of Coulomb, described in the *Encyclopædia* under the word *Electrometer*, and represented in the annexed figure. (1.) In what follows, we shall suppose the reader to have that description before him.



A small horizontal lever *ab*, formed by a very fine thread of gum lac, a powerful insulating substance, is suspended by its centre to a metallic wire, CS., two or three feet long. This lever at one of its extremities, *a*, carries a little ball of the pith of the elder, or a small plane of gilt paper, balanced by a slight swelling formed at *b*, the extremity of the other arm.

The small lever being supposed thus freely suspended and balanced, if we attempt to turn it any number of degrees in the horizontal plane in which it is situated, this cannot be done without twisting in the same degree the metallic wire SC, to which it is attached. But this wire, by virtue of its elastic reaction, will resist the torsion with a force, depending on its dimensions, on its nature, and on its physical constitution; and, according to Coulomb's experiments, so long as its state of aggregation has not received a permanent alteration, by twisting, its resistance will be exactly proportional to the angle by which we withdraw it from its natural position of rest; proportional, therefore, in this case, to the angle which we cause the small horizontal lever *ab*, to describe. (See Biot, *Traité de Physique Experimentale*, Tom. I. and II.) We have only, therefore, to produce this angular deviation by means of the electrical repulsion, and the torsion of the wire will measure its effect. For this purpose, the lever *ab*, being in that position of rest to which the natural equilibrium of the wire tends to carry it, we place beside the ball *a*, another ball A, (fig. 2.) of the same or of a different diameter, but fixed upon an immoveable and insulating support, formed also of a short and very fine thread of gum lac. The two balls being now in contact, we touch the fixed ball A, with the extremity of an electrified tube. The electricity then divides itself between the two balls, the one fixed, the other moveable; these fly from each other, and this repulsion forces the lever, *ab*, to turn round its centre, (fig. 3.) until the repulsive force, weakened by the distance, is exactly balanced by the force of torsion of the suspending wire SC. Hence arises a state of equilibrium which is attained after several oscillations. We now observe, upon a divided circle which surrounds the apparatus, the arc A*a*, which the lever has described; and turning the button S, by which the wire is suspended, and which is itself divided on the circumference, we twist it round a certain number of degrees, until the angular distance of the balls becomes the half, the fourth, the eighth, or any other fraction of what it was at first; and then by comparing the degrees of torsion with the angles where the ball *a* stops in every case, we obtain the relative values of the repulsive force at various distances. In this manner it has been found by Coulomb that this force, like that of the celestial attraction, is rigorously proportional to the quantity of free electricity upon each body, and reciprocally as the square of their mutual distance. An experiment of a similar kind demonstrates, that the same law extends also to the attractive force of the bodies charged with different electricities, and the sensibility of the apparatus is such, that no doubt can remain of the accuracy of the result. The only source of error would arise from the waste of electricity which is continually going on, through the air, and through the supports of gum lac, which, though highly insulating, can never be obtained in this respect altogether perfect. But the above mode of experimenting may itself serve to estimate the effects of these two causes. For we have only to leave the two bodies *a* and A near each other for a considerable time, several hours for example, taking care to untwist, from time to time, the wire SC, in order to diminish its resistance, and replace the balls at the same distance from each other, in proportion as their repulsive force diminishes by the progressive waste of the electricity which covers them. It is easy to conceive that experiments of this nature, properly varied, ought to show the law of the waste of electricity through the air and along the supports. It was, accordingly, in this manner that Coulomb determined it; he was thus enabled to correct all his results, and to bring them up to the mathematical case of air perfectly dry, and of supports completely insulating; and it is with these corrections that the law of the squares of the distances comes out with the utmost rigour, as above enunciated. The apparatus employed by him for this purpose, and which we have explained (fig. 2, 3), he called the *electrical balance*.



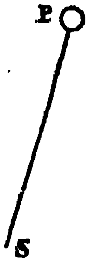


What renders the torsion of the metallic wires peculiarly adapted for these kind of experiments is its extreme sensibility, by which the slightest variation in the intensity of the attractive or repulsive force produces an enormous change in the angle of torsion, which we must communicate to the metallic wire in order to balance it. In the experiments, for example, related by Coulomb,—to turn the lever *ab* a whole circumference, it was only necessary to apply to one of its extremities a force equal to the weight of $\frac{1}{279}$ of a Troy grain.

Another remarkable result presents itself in these experiments. Whatever be the matter of which the balls are composed, provided that they are electrified simultaneously as we have supposed, the electricity divides itself between them always in the same ratio. If they are equal in volume, this ratio is that of equality; if they are unequal, the allotment follows a proportion depending on their diameters; but the chemical nature of the substance has no influence whatever. This may be proved by the following experiment: When the moveable ball *a*, of the balance, has been electrified simultaneously with the fixed ball A, and has receded to a certain distance, where the repulsive force maintains it in equilibrio with the force of torsion of the wire; touch the fixed ball A, with another ball of the same diameter insulated at the extremity of a small cylinder of gum lac, and withdraw it immediately after the contact; the electricity of the fixed ball will now be reduced exactly one-half, as the moveable ball will indicate by the new distance at which it will place itself. Now, this same reduction of one-half takes place whatever be the chemical nature of the ball with which the contact is effected. This fact proves, that the electricity is not retained in the balls by a chemical affinity for the material substance of which they are composed; and thus furnishes one great character which the theory must admit and represent.

In place of balls, we may equally well employ in these experiments small circular disks of gilt paper; or any other bodies, whatever be their form, provided their dimensions are very small, compared with the distance at which we make them act upon each other; this condition is, in fact, the only one which is necessary for making all the quantities of electricity which they possess to act together as if they were united in one single point. But the spherical form, and the circular, have peculiar advantages, arising even from the very manner in which electricity disposes itself in the bodies where it is in equilibrio, as we shall afterwards explain.

This mode of disposition is the first thing to which we must now attend. For, if we succeed in determining it by experiment, it will furnish us with geometrical characters, which the theory ought to satisfy, and which consequently will throw light upon the conceptions by which electricity may be represented. This determination is still obtained by means of the torsion balance. For this purpose we prepare a small circular disk of gilt paper, P. (fig. 4.) which we insulate by fixing it to the extremity of a very fine cylinder of gum lac, SP; we insulate also, as completely as possible, the body which we mean to study, and then electrify it by communicating a spark drawn from a Leyden phial, or an electrophorus. If we now wish to know the state of any of the points of its surface, we touch this point with the little gilt disk, which we shall call the *proof plane*, and which, in this experiment, we hold by the extremity S of its insulating support, SP. We then carry this plane in the electrical balance, where the moveable ball has been previously charged with an electricity of the same kind, and place it for an instant in contact with the fixed ball. We then withdraw it, and the fixed ball being now electrified in the same manner as the moveable one, repels this with a force measured by the angle of torsion, at which the moveable ball stops. While the little plane and the balls of the balance remain the same, the division of the electricity between the little plane and the moveable ball, follows a constant proportion; thus the repulsive force which results, and which drives off the moveable ball, is proportional to the quantity of electricity with which the little plane is charged. But, moreover, experience proves that this is proportional to the quantity of electricity which really exists at the point of the body where we made the contact. The repulsive force, therefore, exerted by the fixed ball, is, likewise, proportional to that quantity of electricity, and thus the torsion observed will give us its measure. By repeating the same proof upon various other points of the body which we submit to experiment, we may determine the manner in which the electricity is distributed throughout.



This supposes only that the body and the balls of the balance are perfectly insulated, and lose none of their electricity while the experiments last. This constancy can never be made to hold with rigour, but we can correct its effect in a very simple manner. For this purpose, compare all the points m, m', m'', of the body with a single point, which we shall denote by M. To compare the state of m, begin by touching M with the proof plane, and determine by means of the torsion balance, the intensity of the repulsive force. Then, having deprived the fixed ball of the electricity which had been communicated to it in this experiment, touch m with the proof plane, and determine, in like manner, the repulsive force which results. Observe the time that elapses between these two comparisons, and suppose, for example, that it is a minute. In a minute after the second experiment, try again the state of M, and take the mean of the two values of the repulsive force, which this point will have furnished. The second will be weaker than if M and m had been both tried at the same time; but the first will be stronger; and if the waste is very slow, as the precautions we have indicated suppose it to be, the arithmetical mean between the two results will be the same that would have been obtained at the intermediate instant, that is to say, when the observation was made upon the point m. This corrective process, so simple and so exact, was imagined and employed by Coulomb, who, in general, has left but little to be added as to the use of his ingenious apparatus.

The method of *alternate contacts* which we have explained, may be employed to discover the disposition of electricity, not only at the surface of bodies, but even in their interior. For this purpose, it is sufficient to pierce in the body a small canal, terminating on its surface, and to plunge the proof plane to the bottom of this canal, when the body is electrified and insulated. In this manner the remarkable result has been obtained, that whatever be the external figure and substance of the body, provided it be a conductor, the electricity will remain nowhere in its interior. It will confine itself entirely to its surface, where it will form a stratum infinitely thin; and this fact, demonstrated by Coulomb, forms another capital basis for the theory.

In regard to the distribution on the surface, it depends on the form of the body. In spheres, for example, the electricity is distributed in a spherical stratum of a constant thickness. On an ellipsoid of revolution, the thickness is variable. The exterior surface of the stratum is that of the body itself, and the quantities of electricity at the extremities of the greater axis are proportional to its length. Lengthen, then, considerably, the ellipsoid, and the thickness of the stratum will augment at the extremities of its greater axis in the same proportion. If the resulting force of repulsion is then sufficiently powerful to overcome the resistance which the ambient air presents to it, the electricity will escape by the points; and this gives the reason that it escapes at the corners of all angular bodies. In general, whatever be the exterior form of the electrified body, this form constitutes the exterior surface of the electrical stratum. As to the interior surface, it always differs infinitely little from the first. But its determination can only be expressed by analytical conditions, deduced from theory, and which experiment demonstrates to be conformable to the truth.

The method of alternate contacts serves also to measure another phenomenon of capital importance. This is the developement of electricity in conducting bodies *by the influence at a distance*, of bodies already electrified. When a body A, for example, which we shall suppose, for greater simplicity, to be spherical, has been electrified and insulated, if we then bring within a certain distance of it a body B, a conductor of electricity, and equally well insulated, but not previously electrified; this latter, as it approaches the other, begins to give signs of electricity; it ceases, however, to do so when we remove it again to a great distance, and it recovers this virtue, or loses it, according as we expose it to, or withdraw it from, the influence of the body already electrified. The philosophers who first discovered this fact supposed, in order to explain it, that every electrified body sent forth electrical emanations, which spread around it *like an atmosphere*, and electrified every conducting body which one might plunge into it. But as this effect is produced even through bodies such as glass, for example, which do not allow the electricity to pass through their substance, it is evident, that, if we wish not to go beyond the facts, we ought not to view this but as a certain influence exerted at a distance, like what is observed in the celestial attraction, and in the magnetic attractions and repulsions. Now, to study the effects and the laws of this influence, we must place the conducting and insulated body B, before the electrified body A, and so near it as to give evident signs of electricity; then touch different points of its surface with the proof plane, and study with the electric balance the nature and the quantity of the electricity which is developed in each of them. In making this experiment we find the following result: The electricity developed in B is not every where of the same nature; it is similar to that of A in the portion of B which is most distant from A, and different in that which is nearest. If A, for example, is charged with vitreous electricity, the anterior part of B, that towards A, is in the resinous, the posterior, in the vitreous state; and between these two extremes each of the two electricities extends in a certain zone, which may be determined by the proof plane. But in all cases the total quantities of the different electricities distributed over these zones have the remarkable property of being exactly equal, so that, if left to themselves, they would neutralize each other's effect. This supposes that B, before being submitted to the influence of A, was in the natural state; but if it has already received a certain quantity of electricity, we then find that the sums of the vitreous and resinous electricities which it possesses under the influence of A, do not differ from each other but by this primitive quantity; and hence we re-obtain it entire when we withdraw B from the influence of A, and deliver it to its natural state of electrical equilibrium. In every case, however, as it is natural to expect, this constancy only holds when we suppose the body B to lose none of its primitive or acquired electricity, either by the contact of the air, or the imperfection of the insulating supports. It is understood, therefore, that we correct the effect of these two sources of waste, by the laws already mentioned, which are determined for each of them by experiment. With the same condition we may study the electricity of A by the proof plane, either when it is abandoned to itself, or when it acts on B; and in this manner, we find that this action takes away from it absolutely nothing of its primitive electricity; but that when B is near A, and influenced by it, A is also influenced in its turn, so that the electricity we have given it is distributed in a different manner; and if the distance of B is small, or the reciprocal action energetic, the electricity ceases even to be of the same nature over all the surface of A. The part nearest to B takes the contrary electricity to that which the anterior part of B possesses, and the more distant takes the opposite. In a word, every thing here is reciprocal, in regard to the two bodies, and the effects are only in proportion to the difference of their form, and of the quantities of external electricity which they primitively possessed.

The enunciation alone of these results is sufficient to point out the consequences. *1st*, Since the body B takes nothing from the electrified body A, it must possess within itself the principles of the two electricities which are developed in it by the influence of this body. *2dly*, Since these two electricities disappear when the influence of the external body ceases, although they cannot escape into the ground, on account of the insulation of B, their proportions must be such, that, being left to themselves, they will mutually neutralize each other. *3dly*, This neutralization must operate without destroying these electricities, since they appear anew and quite entire every time we submit the body B reduced to its natural state, to the influence of the electrified body A.

We are thus led to discover, that the principles of the two electricities exist naturally in every conducting body, in a state of combination which neutralizes their effects. This we shall henceforth call the *natural state of bodies*. We see also that friction, which seems, at first view, a method of generating the two electricities, serves only to disengage them from their mutual combination, and to render the one of them sensible by absorbing the other; and this is the reason, without doubt, that we constantly observe the rubbing and the rubbed body exhibit contrary electricities. In fine, since the sole influence of an electrified body presented at a distance to another body in the natural state, forces the two electricities of that body to separate and to distribute themselves in such a manner that those of a different nature become the nearest to each other upon the two bodies, and those of the same nature the farthest, we must, in order to enunciate this fact, admit, that the electrical principles *of a different name attract, and those of the same name repel, each other*, according to laws which experience may perhaps enable us hereafter to determine.

These observations lead to another important consequence. When we begin to examine the electrical phenomena, we perceive that electrified bodies attract, or seem to attract, all the light bodies which are presented to them, without there being any necessity, for this purpose, of developing first the electric faculty in these, either by friction or communication. But we must now conceive, that this developement goes on of itself, by the sole influence at a distance of the electrified body, on the combined electricities of the little bodies which we present to it; so that, even in this case, the attraction, whether real or apparent, that we observe, does not take place but between bodies that are really electrified.

Moreover, the developement of the combined electricities in these circumstances is indispensable, in order that the attraction may take place; for the latter is always the less vigorous as the former is effected with less facility. To be convinced of this, take two threads of raw silk, very fine, and of equal lengths. Suspend to them two little balls of equal dimensions, of which the one is of pure gum lac, and the other also of gum lac, but gilt on its surface, or coated with tin-foil; these two pendulums being then placed beside each other, and at a small distance, bring near them a tube of glass or of sealing wax, rubbed and electrified; you will see that the ball covered with metal, and on whose surface the decomposition of the combined electricities goes on with facility, will be much more readily and more vigorously attracted than the other. This one will not begin to be attracted till after a certain time, when the decomposition is finally effected on its surface in spite of the resistance which its substance opposes to the motion of electricity; and, in like manner, when once the decomposition has taken place on this ball, its electrical state subsists even after we withdraw the electrified body. The first ball, although gilt, contracts also in this manner a permanent electricity, because the resin of which we suppose it composed, impregnates itself with the electricity developed at its surface; and both of them are favoured in this respect by the contact of the air, which, under the influence of the electrified tube, tends, above all, to take away from them that part of their combined electricities which is repelled by this body; while it has less effect on that of which the repulsive force is disguised by the tube's attraction. Hence we observe, in general, that insulated bodies which have been for some time under the influence of an electrified body come, at last, to have an excess of electricity of the opposite kind, and of which the effects become manifest when we again withdraw them from the influence of this body.

As the results to which we have now arrived are of continual use in the developement and connection of electrical phenomena, it is necessary to reduce them to a kind of theorem, which we shall enunciate in the following manner:

When a conducting and insulated body B, in its natural state, is placed near another body A, electrified and insulated, the electricity distributed over the surface of A acts, by influence, on the two combined electricities of B, decomposes a quantity proportional to the intensity of its action, and resolves it into its two constituent principles. Of the two electricities thus liberated, it repels that of the same and attracts that of a different name with itself. The first diffuses itself over that part of the surface of B which is farthest from A, and the second over that which is nearest. Both being now at liberty, they act in their turn on the free, and even on the combined electricities of A, which, by this re-action, are partly decomposed, and, if A is also a conductor, are separated. This new separation produces a new decomposition of the combined electricity of B, and the same process goes on until the quantities of each principle, liberated upon the two bodies, attain an equilibrium, by a balance of all the attractive and repulsive forces which they exert on one another, in consequence of the similar or contrary nature of each.

Having thus discovered, in general, the attractive and repulsive properties belonging to the two electricities, the vitreous and the resinous,—having discovered their natural state of combination in bodies,—their separation by the influence of a body at a distance, and the general consequences which result from these new properties, we must, according to the philosophical method now adopted in the sciences, endeavour to submit them to calculation; so as to ascertain exactly the detail of the facts, and to anticipate, for example, in regard to each of the electrified bodies which we cause mutually to act on one another, what will be, on any point of its surface, the quantity and the nature of the electricity.

But as we have found that the effects of these mutual influences, such as we have observed them, arise from actions between the electrical principles themselves, it is easy to conceive that we cannot arrive at their cause without determining the nature and the mode of action of these principles; or, what is the same thing *to us*, imagining, according to the phenomena observed, some calculable mode of action which will represent exactly the phenomena, and which can be verified, if not immediately as to its physical existence, at least indirectly, but with certainty, in its consequences.

But if we consider the extreme facility with which the two electricities, the vitreous and the resinous, diffuse themselves in conducting bodies, and advance towards their surfaces where they are retained by the pressure of the air; if we consider the perfect mobility with which these two principles approach and recede from each other, unite themselves, or separate, without losing any of their original properties; it will be obvious, that the most probable idea we can obtain of their nature, is to regard them as fluids of perfect fluidity, whose particles are endowed with attractive and repulsive powers, and which arrange themselves in the bodies where they can move with liberty, in such a manner as to be in equilibrio, by virtue of all the interior and exterior forces which act upon them.

It is easy to see that each of these fluids must possess in itself a cause of repulsion, which tends to separate its particles from each other. For, if we suppose a certain quantity of vitreous or of resinous electricity, introduced into a sphere of metal where its motions are free, we know that it will diffuse itself entirely at the surface, where it will form a stratum of a very small thickness. If we augment the diameter of the sphere, the electrical stratum will always recede more and more from its centre, diminishing at the same time its thickness. If we at last withdraw altogether the pressure of the air, the electricity will be completely dissipated. These effects indicate with certainty a repulsive action exerted between the electrical particles of the same nature, and all the phenomena in which the combined electricities are separated from each other by influence at a distance, confirm completely this result, and at the same time also demonstrate the existence of a reciprocal attraction between the electricities of a different nature.

We see also from these phenomena that the attractions and repulsions become weaker in proportion as the distance increases; but according to what law? Among all those which can be tried, there is one which represents and reproduces completely all the phenomena; it is that of the inverse ratio of the squares of the distances. Adopting this law, then, the constitutions of the two electrical principles will be comprised in the following enunciation: *Each of the two electrical principles is a fluid, whose particles, perfectly moveable, mutually repel each other, and attract those of the other principle, with forces reciprocally as the square of the distance. Also at equal distances the attractive power is equal to the repulsive.* This equality is necessary in order that in a body, in the natural state, the two combined electricities may not exert any action at a distance.

Having thus defined very precisely the characters and the mode of action of the two fluids, we must now explain the mathematical consequences of this definition, in order to compare them with the phenomena, and to see if they are exactly conformable to them. We must endeavour, above all, to find those which, being susceptible of a precise and numerical value, admit of greater rigour in their verification. But these deductions cannot be obtained but by very profound calculations, which require all the resources of analysis; and, even with the aid of these, it is only of late that they have been established in a general and exact manner. It is to M. Poisson that this fine discovery is due. We shall take from his treatise, published in the *Memoirs of the Institute of France* for 1811, the precise results which calculation has made known to him; we shall borrow them as the rigorous deductions of our first definitions; and it will then only remain for us to ascertain if they agree with the facts.

We shall begin with considering a single conducting and insulated body charged with an excess of vitreous or of resinous electricity, and exempt from all external influence. Setting out from the constitution assigned to the two fluids, calculation informs us, that the fluid introduced into this body will diffuse itself entirely on its surface, and will there form a stratum extremely thin. This is confirmed by observations the most minutely exact. Calculation determines also the interior surface of this stratum and its thickness. The exterior surface, bounded by the air, is the same with that of the body. The air is in this case to electricity, as an impenetrable vase of a given form, which contains it in its interior capacity, and resists by its pressure the tendency which it has to escape.

The interior surface is in every case but very little different from the other, the electrical stratum being very thin. But in order that the electrical state of the body may remain permanent, the form of this surface must be such, that the entire stratum exert neither attraction nor repulsion on the points comprised within its cavity. For, if these actions were not reduced to nothing, they would operate upon the combined electricities of the body, would decompose part of them, and the electrical state of the body would therefore change, contrary to the state of permanency which we have supposed. The analytical condition which establishes this property, determines the form and the thickness of the stratum, which may, and, even in general must, be unequal upon the different parts of the surface of the electrified body. (See the *Memoirs of the Institute of France* for 1811.) If the body, for example, has the form of a sphere, the two surfaces of the electrical stratum will be spherical, and will have their centre in the centre of the sphere. The thickness of the stratum then will be everywhere constant, and equal to the difference of their radii. Newton, indeed, has long since demonstrated, that, in the law of the square of the distance, such a stratum exerts no action on the points which are within. (*Princip. Math.* Lib. 1. Prop. LXX.)

If the proposed spheroid is an elipsoid, the interior surface of the electrical stratum will be also an ellipsoid, concentric and similar; for it can be demonstrated, that an elliptical stratum, of which the surfaces are also concentric and similar, exerts no action on a point situated in its interior. The thickness of the stratum in every point is determined generally by this construction. It hence follows, that this thickness is greatest at the extremity of the greater axis, and least at the extremity of the smaller; and the thicknesses corresponding to the two extremities of the different axes, are to each other as the lengths of these axes, which, as we have seen, is conform to the experiments. In general, the exterior surface of the fluid stratum is given by the surface of the body itself; and the whole problem is reduced to find for the interior surface a form very little different from this, which shall bring to nothing the total action of the stratum on all the points comprised within its cavity.

The electrical stratum thus disposed, acts by attraction and repulsion on the other electrical particles situated beyond its exterior surface, or at this surface itself. It attracts them if they are of a different nature from its own, and if they are of the same nature it repels them. This last case is that of the electrical particles which form the exterior surface of the stratum, each of these being repelled from within outwards, with a force proportional to the thickness of the stratum at that point. The particles situated under the surface, in the thickness of the stratum itself, suffer a similar repulsion, but weaker, as it is only proportional to the thickness which separates them from the interior surface of the stratum, for the particles with which they are enveloped on the side of the exterior surface, according to the form of the two strata, exert on them no action at all. All these repulsive forces gradually decreasing, and being resisted in their effects by the external air, which opposes the escape of the electrical particles, it is easy to conceive, that there must result a *total pressure* exerted against this air, and tending to drive it off. This pressure is in a ratio compounded of the repulsive force exerted at the surface, and of the thickness of the stratum; or, as the one of these elements is always proportional to the other, we may say that, in every point, the pressure is proportional to the square of the thickness. It may therefore in general be variable on the surface of electrified bodies.

If this pressure is everywhere less than the resistance which the air opposes, the electricity is retained in the *vase* of air, and cannot escape. But if the pressure, in certain points of the surface, comes to exceed the resistance of the air, then the *vase* breaks, and the fluid escapes through the opening. This is what happens towards the extremities of the points, and on the sharp corners of angular bodies. For it can be demonstrated, that at the summit of a cone, for example, the pressure of the electric fluid would become infinite, if the electricity were allowed to accumulate there. At the surface of an elongated ellipsoid of revolution, the pressure does not become infinite at any point; but it will be so much the more considerable at the two poles, as the axis which joins them is greater in relation to the diameter of the equator. According to the theorems already cited, this pressure will be to that which takes place at the equator of the same body, as the square of the axis of the poles is to the square of the axis of the equator; so that, if the ellipsoid is very much elongated, the electric pressure may be very feeble at the equator, while at the poles it will surpass the resistance of the air. Hence, also, when we electrify a metallic bar, which has the form of a very long ellipsoid, the electric fluid runs principally towards its two extremities, and escapes by these points, in consequence of its excess of pressure above the resistance of the air which opposes it. In general, the indefinite increase of the electric pressure in certain points of electrified bodies, furnishes a natural and exact explanation of the faculty which points possess, of dissipating with rapidity into the non-conducting air the electric fluid with which they are charged.

If the nature of the electrified body were such that the electricity could not move freely in it, the excess of pressure, of which we have been speaking, would exert itself against the particles themselves of the body which envelope the electric stratum; or, in general, against those which, either by their affinity, or by any other mode of resistance, would oppose its dissipation.

Having determined, according to the theory, the manner in which electricity disposes itself in a single conducting body, insulated and unaffected by any external influence, let us pass to the more complicated case, where several electrified and conducting bodies act mutually on each other; and as it is necessary to make choice of bodies whose form renders the phenomena accessible to calculation, let us consider two spheres of some conducting substance, both electrified and placed in presence of each other at any distance.

The disposition of electricity in these circumstances, and in all those where several electrified bodies are submitted to their mutual influence, depends on a general principle, evident in itself, and which has the valuable advantage of reducing all these questions to a mathematical condition. The following is its enunciation, which we take from the treatise of M. Poisson.

If several electrified bodies are placed near each other, and if they arrive at a permanent state of electricity, it is necessary in this state that the resulting effect of the actions of the electric strata which cover them, upon any point taken in the interior of these bodies, be nothing. For if this resulting force were not nothing, the combined electricity which exists at the point in question would be decomposed, and the electrical state would change, contrary to the supposition which we have made of its permanency.

This principle, translated into the language of the calculus, furnishes immediately as many equations as we consider bodies, and as there are unknown quantities in the problem. But their resolution often surpasses the powers of analysis. M. Poisson, however, who has so happily discovered the general key of this theory, has at last surmounted all the analytical difficulties, for the case of two spheres placed in contact or near to each other, and primitively charged with any quantities of electricity. The formulæ to which he has arrived afford a great number of results which can be verified by experiment, and which form so many severe tests of the justness of the theory. Besides the interest which such verification must always present, we will obtain in them the farther advantage of fixing our ideas with precision on the most delicate phenomena which electricity produces.

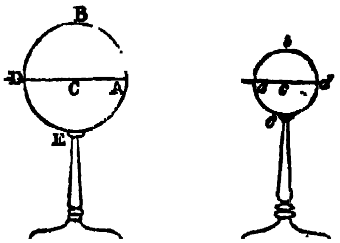
Suppose, *first*, the two spheres in contact, and charged with either electricity, vitreous or resinous, calculation shows that there is no free electricity at the point of contact. From thence the thickness of the electric stratum goes on increasing on each of the spheres, according to a law which depends on the relation of their radii, but it attains always its maximum on the opposite side, on the line of the two centres. If we separate the two spheres, each of them preserves the same quantity of electricity which it has attained during the contact, and these quantities have to each other a relation which the calculation assigns according to the proportion of the radii.

The verification of these results is effected with the greatest facility, by means of the small proof plane, and by the general method of alternate contacts explained above. In this manner the indications of the theory are found to be confirmed by experiment in their minutest details; that is to say, that, on introducing into the theoretical formulæ the diameters of the spheres on which we operate, or only the relations of these diameters, the calculus shows in advance, and as exactly even as the observations themselves, the law of the distribution of electricity over the two spheres, as well as the proportion of its intensity on each. There is no occasion, even for this purpose, of new experiments; for we may take those which have been already made by Coulomb, and have for a long time been published in the *Transactions of the Academy of Sciences*; and, accordingly, it is with these previous results, whose priority, indeed, gives them all the authenticity of an incontestible fact, that M. Poisson has compared the numbers given by his theory.

The case of contact being thus completely analysed, let us examine what takes place when the two spheres separated from their contact are removed to a certain distance from each other.

In this case, a very remarkable phenomenon, discovered by Coulomb, is developed, and of which that philosopher determined the measure by his electric balance. We have seen that, during the contact, the electricity is the same on both the spheres. To fix our ideas, suppose it to be the *vitreous*. As yet its intensity is nothing, as we have seen, at the point of contact; but the instant we separate the two spheres, if their dimensions are unequal, this state of things ceases. A part of the combined electricities of the *small sphere* is decomposed, and what is of a contrary nature to that of the large sphere, namely, the resinous in our example, appears in, and near the point where the contact took place. This effect diminishes in proportion as we remove the spheres from each other, and vanishes altogether at a certain distance, which depends on the proportion of their radii. At that distance, the point of the small sphere, where the contact was made, returns to the state in which it was during the contact itself, that is, it has no more any species of electricity. From this position, if we still increase the distance, the electricity remains of the same nature over all the extent of the small sphere, and of the same nature also as it was during the contact. These changes are *always* peculiar to the smallest of the two spheres, whatever be the quantity of electricity which has been previously communicated to either. As to the larger of the two spheres, the electricity is always, and everywhere, of the same nature as at the moment of contact.

To observe these phenomena, we place the two spheres upon solid supports of some insulting substance, and of such a magnitude that their centres may be in a horizontal plane, as represented in the figure. (5.) After having placed them in contact, and electrified them together, we remove them to a small distance, A *a*, from each other. We then carry the proof plane first to A upon the large sphere, to the point where the contact was made; and by trying, not with the electrical balance, but with a very sensible electroscope, the electricity which it carries off, we observe that it is always of the same nature with that upon the rest of the surface ABDE. Making then the same trial at the corresponding point *a*, we find that the electricity in this point is, *first*, of a nature contrary to that of the large sphere; then nothing when the distance becomes a little greater; then of the same nature when the distance becomes still greater; and in this manner, by gradually augmenting the distance, we see the phenomena pass through all the periods which have been already pointed out by the theory. These trials must be all made with the most sensible electroscope, in order to perceive the feeblest signs of either electricity.



In one of Coulomb's experiments, the large globe was twelve inches in diameter, and the small one eight. As long as the distance A *a* was less than an inch, the point *a* gave signs of a contrary electricity to that of the large globe. When the distance became equal to an inch, the electricity of this point became equal to nothing, as at the instant of contact; and, lastly, at every distance beyond this, it became of the same nature with that of the other sphere. The large globe remaining the same as in the preceding experiment, Coulomb gave to the small globe a diameter of only four inches; then the two electricities continued of an opposite nature to the distance of two inches. When this diameter was only two inches and under, the opposition was kept up to the distance of two inches five lines, but no farther.

The comparision of these experiments shows, that the distance A *a*, where the opposition of the electricity ceases, diminishes in proportion as the two globes approach to an equality, and becomes nothing when they become equal. This is a circumstance which is also confirmed by the theory, which equally indicates all the other details of the phenomenon, the relation between the radii of the two globes being given.

That these experiments may succeed well, the air must be very dry; else the electricity of the large globe, escaping through the air, will tend directly to neutralize the weak electricity of the opposite kind, which is developed at the point *a* of the little globe, and the phenomena will become much less sensible, if not entirely disguised.

We have hitherto supposed the two globes to have been brought into contact before being submitted to their mutual influence. This condition establishes between the quantities of electricity, which they possess, a relation that limits the generality of which the problem is susceptible, and to embrace it entirely, we must consider two spheres charged, in any proportion whatever, with electricity of the same or of a different nature; and that they gradually approach each other until they come into contact.

Here the analysis of M. Poisson has anticipated the results of experiment. It is from thence that we shall draw the details into which we are to enter; and which, if they should come one day to be observed, will furnish the severest test to which this analysis can be submitted.

When two electrified spheres are made gradually to approach each other, and when there does not exist between the species and the quantities of electricity which they possess, the particular relation which would be established by their contact, the thickness of the electric stratum at the points nearest each other, on the two surfaces, becomes greater and greater, and increases indefinitely as their distance diminishes. It is the same with the pressure exerted by the electricity against the mass of air intercepted between the two spheres; since the pressure, as we have mentioned above, is always proportional to the square of the thickness of the electric strata. It must at last then overcome the resistance of the air, and the fluid, in escaping under the form of a spark or otherwise, must pass, previous to the contact, from the one surface to the other. The fluid thus accumulated, before the spark takes place, is of a different nature, and of nearly equal intensity on each of the spheres. If they are electrified, the one *vitreously* and the other *resinously*, it is vitreous in the first and resinous in the second; but when they are both electrified in the same manner, vitreously for example, there arises a decomposition of the combined electricity upon the sphere which contains less of the vitreous fluid than it would have in the case of contact; the resinous electricity, resulting from this decomposition, flows towards the point where the spark is preparing, and, on the contrary, the other sphere, which contains more vitreous electricity than it would have after the contact, remains vitreous over its whole extent.

The phenomena are no more the same after the two spheres have been brought in contact together, and are then removed, however little, from each other. The ratio which then exists between the total quantities of electricity with which they are charged, causes to disappear in the expression of the thickness, the term which before became infinitely great for a distance infinitely small, and no spark takes place. The electricity of the points nearest each other upon the two spheres is then very feeble, for very small distances, according to a law which calculation determines, and its intensity is nearly the same on both spheres; but when they are unequal, this electricity is vitreous on the one, resinous on the other; and it is *always upon the smallest* that it becomes of a nature contrary to the total electricity, which is conformable to the observations related above.

In general, all the varieties of these phenomena depend on the relation which we establish between the radii of the two spheres, and also between the quantities of electricity with which they are charged. We may even determine these proportions in such a manner, that, at a certain distance, the thickness of the electric stratum on the small sphere may be almost constant, so that this sphere may remain near the other, almost as if it were not exposed to any action, not from the weakness of the electricity on the other sphere, but in consequence of a sort of equilibrium which is then established between its action upon the smallest, and the re-action of this upon itself. In this case, the electricity diffused over the large sphere is vitreous in certain parts, resinous in others, and its thickness in different points presents very considerable variations. M. Poisson has determined the proportions of volume and of electric charge necessary to produce these phenomena; and, in this respect, as we have formerly observed, his analysis has anticipated the observations.

To complete the case of two electrified spheres placed in presence of each other, M. Poisson has calculated the changes which the greater or less distance produces on the state of the points most distant from those where the contact takes place. In this respect he has found, that, in proportion as the two spheres approach each other, the thicknesses of the electric stratum in these points tend more and more towards the values which they would have at the instant of contact. As they arrive at this limit, however, but very slowly, it hence follows, that even at very small distances, they differ yet much from what they would be if the contact or the spark actually took place. Hence we conclude also, that the spark, when it takes place at a sensible distance, changes suddenly the distribution of the electricity over the whole extent of the two surfaces, from the point where it is produced even to that which is diametrically opposite. This re-action is easily verified by experiment; we have only to fix, at certain distances from each other, along an insulated conductor, couples of linen threads, with pith balls suspended to them, and to communicate to this conductor a certain quantity of electricity, by which the threads may be made to diverge; if we then draw successively several sparks by the contact of an insulated sphere, whose volume is not too small, all the threads will be observed to be disturbed, and shaken in a manner by each explosion, in whatever part of the conductor it is produced.

For the particular case in which the two electrified spheres are removed to a great distance from each other, in relation to the radius of any one of them, M. Poisson has discovered formulæ which express in a very simple manner the thickness of the electric stratum, in any point of their surfaces. We shall here state these formulæ, as they enable us to explain distinctly *why* conducting bodies, when they are electrified, *seem* to attract or repel each other, although, from the manner in which electricity is distributed among them, and from its mobility in their interior, we cannot suppose that these phenomena indicate any sensible affinity which it has for their substance. Let r,r' represent the radii of the two spheres; call e,e' the thicknesses of the strata which the quantities of electricity they possess would form upon their surfaces if they were left to themselves, and exempt from all external influence; call a the distance of their centres, and place them so far from each other that the radius r' of one of them be very small compared with a, and with $a - r$. Lastly, let u,u' denote the angles formed with the distance a, by the radii drawn from the centre of each sphere to any point on their surfaces; then the thicknesses E,E′ of the electric stratum in these points will be expressed approximately by the following formulæ.

$$\mathrm{E} = e + \frac{e'r'^2}{ar} - \frac{e'r'^2\,(a^2 - r^2)}{r\,(a^2 - 2\,ar\cos.u + r^2)^{\frac{3}{2}}}$$

$$\mathrm{E}' = e' - \frac{3\,er^2}{a^2}\cos.u' + \frac{5\,er^2r'}{2\,a^3}\,(1 - 3\cos.^2 u')$$

Here, as in the experiments of Coulomb, the angles u,u' are reckoned from the points A and a

(fig. 5), in which the surfaces of the two spheres would touch each other, if we brought them to the point of contact. The difference of symmetry in these expressions is owing to this, that the approximation from which they arise supposes the radius r', of the second, very small compared with the distance $a - r$, which separates its centre from the surface of the other.

If it is required, for example, from these formulæ to determine the state of an insulated, but not electrified sphere, which we present to the influence of another sphere charged with a certain quantity of electricity, we have only to suppose e' nothing in the equation of the second sphere, and it will then become

$$E' = \frac{-3cr^2}{a^2}\left[\cos. u' + (3 \cos.^2 u' - 1)\frac{5r'}{6a}\right]$$

At the point a, on the line Aa, between the two centres, the angle u' is nothing. In this point then we have $\cos. u' = 1$: and $E' = -\frac{3er^2}{a^2}\left(1 + \frac{5r'}{3a}\right)$

The thickness E′, then, has always a contrary sign to that of e, that is to say, that the electricity on this point, in the sphere of which the radius is r', is of a nature contrary to that which covers the sphere of which the radius is r.

At the point d, diametrically opposite to the preceding, the angle u' is equal to 180°, which gives $\cos. u' = -1$; and $E' = +\frac{3er^2}{a^2}\left(1 - \frac{5r'}{3a}\right)$

This value of E′ has always the same sign with that of e; for the factor $\frac{5r'}{3a}$ is a fraction far smaller than unity, since the distance a is supposed very great, compared with the radius r'; then the electric stratum will be in this point of the same nature as upon the other sphere.

Thus we see arising out of the theory the important result which we have until now only established by experiment, that while a sphere c, not electrified, is placed in presence of another sphere C, electrified vitreously, for example, the combined electricities of c are partly decomposed; the resinous electricity that results flowing towards the part of c which is nearest to C, and the vitreous electricity towards the part which is farthest from it.

The thicknesses of the stratum in these two points are to each other in the ratio of

$$1 + \frac{5r'}{3a} \text{ to } 1 - \frac{5r'}{3a};$$

they are nearly equal, then, since a is supposed very great in relation to r'.

Hence it may be conceived that there must be upon the sphere c a series of points, in which the thickness of the electric stratum is nothing, and which form a curve of separation between the two fluids. The *locus* of these points will be found by putting the general expression of the thickness E′ equal to zero, which gives the condition

$$0 = \cos. u' + (3 \cos.^2 u' - 1)\frac{5r'}{6a}.$$

If the distance a were altogether infinite, compared with the radius r', the second member of this equation would be reduced to $\cos. u'$; consequently, this cosine would be 0, which would give $u' = 90°$. The line of separation of the two fluids would then be the circumference of the great circle, of which the plane is perpendicular to the line of the centres.

But if a is not infinite, it is at least very great relatively to r'. Thus, the factor $\frac{5r'}{6a}$ will still be very small fraction, and the true value of $\cos. u'$ will be equally so. We may, therefore, in calculating, neglect the product of $\frac{5r'}{6a}$ by $\cos.^2 u'$, compared with the product of this same quantity by unity. With this modification the equation resolves itself and gives

$$\text{Cos.}\, u' = \frac{5r'}{6a}.$$

In this case the line of separation of the two fluids is still a circle whose plane is perpendicular to the line of the centres; but the distance of this plane from the centre of the sphere, in place of being nothing, is equal to $r' \cos. u'$ or $\frac{5r'^2}{6a}$, this distance being taken from c to a, towards the electrified sphere C.

In considering only the degree of the equation which determines generally $\cos. u'$, there would seem to be two values of this cosine which would satisfy the conditions of our problem; but it will clearly appear, that one of those roots should necessarily be greater than unity, and consequently, will not have here any real application, as it would correspond to an arc u', which is imaginary.

When we now consider how various, how delicate, and how detached from each other, are the phenomena this theory embraces; with what exactness also, it represents them, and follows, in a manner, all the windings of experiment, we must be convinced that it is one of the best established in physics, and that it bestows on the real existence of the two electric fluids the highest degree of probability, if not an absolute certainty. But what is not less valuable for science, it teaches us to fix, by exact definitions, the true meaning which we must attach to certain elements of the electrical phenomena, which are too often vaguely enunciated, or even confounded, with others; although the knowledge of each of them, individually, is indispensable to form a correct and general idea of the phenomena.

The first of these elements is the *species*, vitreous or resinous, of the electricity which exists at the surface of an electrified body, and at every point of this surface. This is determined by touching it with the proof plane, and presenting this to the needle of the electroscope, already charged with a known species of electricity.

The second element is the *quantity* of this electricity accumulated on every point, or, what comes to the same thing, *the thickness of the electric stratum.* This we still measure by touching the body with the proof plane, and communicating the electricity acquired by this contact to the fixed ball of the electric balance, the moveable one having been previously charged with electricity of the same nature. The force of torsion necessary to balance the electric reaction communicated by the plane to the fixed ball, is at equal distances proportional to the quantity of electricity which it possesses, or, what is the same thing, to the thickness of the electric stratum on the element of the surface which it has touched.

The third element which it is of importance to consider in the phenomena, is the *attractive or repulsive action* exerted by each element of the electric stratum upon a particle of the fluid situated at its exterior surface or beyond this surface. This attraction or repulsion is directly proportional to the thickness of the electric stratum on the superficial element which attracts or repels, and is inversely proportional to the square of the distance which separates this element from the point attracted or repelled.

In fine, the last element to be considered, and which is a consequence of the preceding ones, is the *pressure* which the electricity exerts against the external air in each point of the surface of the electrified body. The intensity of this pressure is proportional to the square of the thickness of the electric stratum.

By adhering strictly to these denominations, there will be no risk of falling into error from vague considerations; and if we also keep in mind the developement of electricity by influence at a distance, we shall then find no difficulty in explaining all the electric phenomena.

To place this truth in its full light, we shall apply it to some general phenomena which, viewed in this manner, can be conceived with perfect clearness, but which, otherwise, do not admit but of vague and embarrassed explications. These phenomena consist in the motions which electrified bodies assume, or tend to assume, when they are placed in presence of each other, and in which they appear as if they really acted upon each other by attraction or by repulsion. But it is extremely difficult to conceive the cause of these movements, when we consider that, according to the experiments, the attraction and repulsion are only exerted between the electric principles themselves, without the material substance of the body, provided it be a conductor, having any influence on their distribution or their displacement. We cannot hence admit, that the particles of the electric principles, whatever they may be, really attract or repel the material particles of the bodies. It is absolutely necessary, therefore, that the attractive and repulsive actions of these principles, whatever they are, be transmitted indirectly to the material bodies, by some mechanism which it is of extreme importance to discover, as it is the true key to these phenomena. But we will see that this mechanism consists in the reaction produced by the resistance which the air and non-conducting bodies in general oppose to the passage of electricity.

For the sake of greater simplicity, we may first confine ourselves to the consideration of two electrified spheres A and B; the one A fixed, the other B moveable. Three cases may arise which it is necessary to discuss separately.

1. A and B non-conductors.
2. A, a non-conductor, B, a conductor.
3. A, a conductor, and B, a conductor.

In the first case, the electric particles are fixed upon the bodies A and B, by the unknown force which produces the non-conductibility. Unable to quit these bodies, they divide with them the motions which their reciprocal action tends to impress upon themselves.

The forces, then, which may produce the motion of B, are, 1. The mutual attraction or repulsion of the fluid of A upon the fluid of B. 2. The repulsion of the fluid of B on itself. But it is demonstrated in mechanics, that the mutual attractions and repulsions exerted by the particles of a system of bodies on each other, cannot impress any motion on its centre of gravity; the effects of this internal action then destroy themselves upon each of the spheres; there cannot result from it any motion of the one towards the other; and the first kind of force, therefore, is the only one to which we need pay any attention. If the electricity is distributed uniformly over every sphere, each of them attracts or repels the other as if its whole electric mass were collected in its centre Thus, if we call a the distance of their centres, r,r their radii, e,e' the thicknesses of the electric strata formed upon their surfaces by the quantities of electricity introduced into them, the electric mass of each of them will be $4\pi r^2e$, $4\pi r'^2e'$, π being the semicircumference of which the radius is equal to unity, and the attractive or repulsive force will be expressed by $\frac{16\pi^2Kr^2r'^2ee'}{a^2}$, K being a coefficient which expresses the intensity of the force when the quantities a, e, e', are each equal to the unity of their species. This force transmits itself directly to the two spheres, in consequence of the adhesion by which they retain the electric particles. We see, from this expression, that the force must become nothing, if e or e' be nothing, that is, if the one of the two spheres be not primitively charged with electricity. During the motion it suffers no alteration but what arises from the distance, because the two spheres being supposed of a perfectly non-conducting substance, their reciprocal action produces upon them no new developement of electricity.

In the second case, where A is a non-conductor, and B a conductor, the sphere B, suffers a decomposition of its natural electricities by the influence of A. The opposite electricities which result from this decomposition, unite with the new quantity which has been introduced, and dispose themselves together according to the laws of the electric equilibrium. Here the motion of B towards A may be regarded under two points of view.

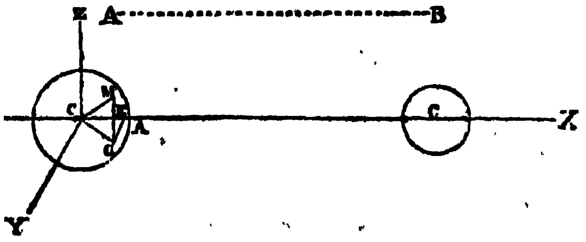
Suppose, first, that without disturbing the electric equilibrium of B, we extend over its surface an insulating stratum, solid, without weight, and which may remain invariably attached to it. The electricity of B, unable to escape, will press as it were against this stratum, and, by this means, transmit to the particles of the body the forces by which it is urged. The forces which then act upon the system will be, 1. The mutual attraction or repulsion of the fluid of A on the fluid of B. 2. The repulsion of the fluid of B upon itself, a repulsion, however, which cannot produce any motion upon the centre of gravity of B. 3. The pressure of the fluid of B upon the insulating envelope, a pressure, again, which being exactly counterbalanced by the reaction of this coating, produces still no motion whatever. The first force, then, is still the only one to which we need pay any attention.

When the distance a, of the two spheres is very great relatively to the radii of their surfaces, the decomposed electricities of B, as we have seen at page 85, are distributed almost equally over the two hemispheres situated on the side of A, and on the opposite. In that case the actions which they suffer on the part of A are nearly equal, and destroy each other; all the force then is produced by the quantities of external electricity, $4\pi r^2 e$, $4\pi r'^2 e'$ introduced into the two spheres, which, acting as if they were wholly collected in their centres, the force becomes

still $16\pi^2 K r^2 r'^2 ee'$.

When the two spheres are very far from each other, the coefficient K may be considered as constant, and the attractive or repulsive force varies not but in consequence of a change in the distance a. But this is only an approximation; for, to consider the matter rigorously, the electrical state of the conducting sphere B, varies in proportion as it approaches A, on account of the separation which this produces in its natural electricities. Hence also the reciprocal action of the two spheres ought to vary in a very complicated manner, and it is probably to this that we must ascribe the error which appears in the experiments of Coulomb, at very small distances, when calculated by the simple law of the square of the distance.

The supposition of an insulating envelope without weight, serves here merely to *connect* the electric fluid with the material particles of the body B, and we may always regard as such the little stratum of air with which bodies are ordinarily enveloped, and which adheres to their surfaces. Yet the same result may be obtained without the aid of this intermediary; but, in that case, we must consider the *pressures* produced upon the air by the electricities which exist at liberty in B. These electricities, in effect, as well those that have been introduced, as those that are decomposed on it, move towards the surface of B, where the air stops them by its pressure, and prevents their escape; they dispose themselves then *under* this surface, as their mutual action and the influence of the body A require, resting, for this purpose, against the air, which prevents them from expanding. But, reciprocally, they press this air from within outwards, and tend to fly off with a force proportional to the square of the thickness of the electric stratum in every point. Decompose these pressures in the direction of three rectangular axes of the co-ordinates $x\ y\ z$, the one x being in the direction of the straight line Cc (fig. 6),



which joins the centres of the two spheres, and add together all the partial sums; it will then be found, as we shall show presently, that, in the direction of the co-ordinates y and z, they amount to nothing, and there only remains, therefore, a single resulting force, directed in the straight line Cc, that is, towards the centre of the sphere A. When the spheres are very distant from each other, compared with the radii of their surfaces, the decomposed electricities of B press the external air, in opposite directions, with a force nearly equal, and their effects destroy each other almost exactly. There only remains, then, the effect of the quantities e, e' introduced into the two spheres, and from this there results an excess of pressure in the direction of the lines of the centres, and expressed by $\frac{Kee'}{a^2}$, K being a constant quantity for the two spheres, that is, exactly the same as was obtained by the other method. It is evident, besides, that this expression is subject to the same limitation, since the pressures produced by the electric stratum against the external air, ought to vary with the quantity of natural electricity decomposed on B by the influence of A, in proportion as the two spheres approach each other.

The third case, in which A and B are both conductors, is resolved exactly upon the same principles, either by imagining the two electrified surfaces covered with an insulating envelope, and calculating the reciprocal actions of the two fluids which are transmitted by means of this cover to the material particles; or in considering the pressures produced on the external air by the two electric strata, and calculating the excess of these pressures in the direction of the line which joins the two centres; only, in this case, the attractive or repulsive force of these two spheres will vary in proportion as they approach each other, not only by the difference which thence arises in the intensity of the electric action, but still farther by the decomposition of the natural electricities which will be going on in the two conducting bodies A and B.

To render the mathematical exactness of these considerations evident, we shall, for the preceding case, go through the calculation of the pressures exerted against the air by the quantities of electricity introduced or developed on the two spheres. This will have, besides, the advantage of giving a new application to the formula stated at p. 84. For this purpose take, first, on the sphere A, fig. 6, any point whatever which we may denote by M. The pressure exerted at this point against the air depends on the thickness of the electric stratum there. To know this, we must put the particular value of the angle u, which corresponds to the point M, in the general expression of E given at page 84, and multiply the square of this thickness by a constant coefficient k, which will disappear of itself, when we take the relations of the pressures among each other at different points. In this manner, the pressure for any point of either sphere calculated for the unity of the surface, will be represented by kE^2 upon the first, and kE'^2 upon the second, E, E′ being taken from the formulæ stated in p. 84. We shall now develope, successively, these two expressions. In the first place, as the pressure kE^2 varies from one point to another with the thickness of the electric stratum, we cannot suppose it the same, but in a very small space all round the point M, a space which must be considered as a superficial element of the sphere, and which we shall call ω; thus the expression KE^2 being calculated for the unity of surface, the pressure upon the small superficial element ω will be $K\omega E^2$. This pressure acts perpendicularly to the spherical surface A, in the direction of the radius CM; decompose it then into three others, parallel to three axes of the rectangular co-ordinates x, y, z, which have their origin at the centre C; the first, x, being in the direction of the straight line, Cc, which joins the centres of the spheres, and the two others perpendicular to this line. To effect this decomposition, we must multiply the normal pressure KE^2 by the cosines of the angles which the radius CM forms with the co-ordinates x, y, z; that is, by $\frac{x}{r}$, $\frac{y}{r}$, $\frac{z}{r}$, since, in the formula of page 84, we have represented by r the value of the radius CM of the sphere A. We will thus have the three following component parts

parallel to the co-ordinates x; $K\frac{x}{r}\omega E^2$

parallel to the co-ordinates y; $K\frac{y}{r}\omega E^2$

parallel to the co-ordinates z; $K\frac{z}{r}\omega E^2$

But we must observe, first, that it is absolutely of no use paying any attention to the two last, because the efforts which each of them makes, on the whole extent of the surface, mutually destroy each other on account of the symmetrical disposition of the electricity relatively to the axis of the co-ordinates x, which joins the two centres. If we consider, in effect, the force, for example, $K\frac{z}{r}\omega E^2$ for the point M, situated in the figure under the plane of the co-ordinates $x\,y$; we shall find, above this plane, another point M′ situated quite similarly, and of which the co-ordinates x, y, z, will consequently be the same, with this only difference, that z will there be negative, on account of its opposite situation relative to the origin of the co-ordinates. For this second point, the element ω, and the pressure KE^2, will be also absolutely the same; ω on account of the symmetry of the surface of the sphere A; E^2 on account of the symmetrical disposition of the electricity round the axis of the co-ordinates x, which joins the centres of the two spheres A and B; but the component force which proceeds parallel to the co-ordinates z, will be $-K\frac{z}{r}\omega E^2$, on account of the negative sign of z; this force, and its analogous one, $+K\frac{z}{r}\omega E^2$ being equal, and in opposite directions, will mutually destroy each other, and a similar equilibrium will be equally obtained, in this kind of pressure, for all the other couples of points M, M′, which correspond on the two sides of the plane of $x\,y$.

A similar process of reasoning will prove that the forces $K\frac{y}{r}\omega E^2$ will destroy each other two and two, upon corresponding points, taken on the two sides of the plane of $x\,z$, and of which the co-ordinates will be $+x$, $+y$, $+z$ for the one, and $+x$, $-y$, $+z$ for the other.

It remains, then, to consider the components of the pressures, taken parallel to the co-ordinates x; that is, parallel to the straight line which joins the centres Cc, of the two spheres; and, indeed, from the symmetrical disposition of electricity round this straight line, it is evident that it cannot have any motion but in this single direction; and, consequently, these components alone must produce the tendency of the two spheres towards each other.

To obtain, in the simplest manner, the sum of all these components, it must be remarked, that their general expression $K\frac{x}{r}\omega E^2$ contains no variable but x; for cos. u, which enters into the value of E^2 is equal to $\frac{x}{r}$; it hence follows, that their intensities are equal in the points relatively to which the co-ordinate x is the same, and which are consequently situated upon one small circle, parallel to the plane of the co-ordinates y, z. Besides, as all these points are equally distant from the line of the centres, it is clear that the total result of the equal forces which are applied to them will be in the direction of this line; consequently this will also be the direction of the general result of all the efforts of this kind exerted upon the whole surface of the sphere A.

To obtain, now, easily, the sum of all these forces, parallel to the line of the centres, which is here that of the co-ordinates x, let us begin by joining together the values of x which are equal and contrary; for the thicknesses E, of the electric stratum on the two hemispheres of A being almost equal, from the supposition that the two spheres are very distant, the pressures corresponding to opposite values $+x$ and $-x$, must be almost equal also; and, as the components which they give parallel to the co-ordinates x are in a contrary direction, their sum must be reduced to a very small quantity. To introduce this circumstance, call $E_{,}$ what E becomes when we change $+x$ into $-x$; then the expressions of the corresponding components parallel to the co-ordinates x will be,

On the side of the positive co-ordinates x,	$+K\frac{x}{r}\varpi E^2$	Tending to move the air in the direction AB
On the side of the negative co-ordinates $-x$,	$-K\frac{x}{r}\varpi E_{,}^2$	Tending to move the air in the direction BA.

We preserve the superficial element ϖ always of the same value, because it is exactly alike in the two cases, on account of the symmetrical form of the sphere on the two sides of the plane of the co-ordinates $y\ z$; adding these two components to each other with their actual sign, their sum will express the element of the total resulting force which tends to carry the air in the direction AB. This, then, will be $K\frac{x}{r}\varpi(E^2-E_{,}^2)$, or, what is the same thing,

$$K\frac{x}{r}\varpi(E+E_{,})(E-E_{,})$$

But, from the formula of p. 84, we have generally

$$E=e+\frac{e'r'^2}{ar}-\frac{e'r'^2(a^2-r^2)}{r(a^2-2ar\cos. u+r^2)^{\frac{1}{2}}}$$

To change $+x$ into $-x$, $+\cos. u$ must become $-\cos. u$, because $\cos. u=\frac{x}{r}$; for this second case, then, we shall have

$$E_{,}=e+\frac{e'r'^2}{ar}-\frac{e'r'^2(a^2-r^2)}{r(a^2+2ar\cos. u+r^2)^{\frac{3}{2}}}$$

consequently, by subtracting these equations from each other, we have

$$E-E_{,}=\frac{e'r'^2(a^2-r^2)}{r}\left\{\frac{1}{(a^2+2ar\cos. u+r^2)^{\frac{3}{2}}}-\frac{1}{(a^2-2ar\cos. u+r^2)^{\frac{3}{2}}}\right\}$$

or, what is the same thing, and is better adapted for approximations,

$$E-E_{,}=\frac{e'r'^2\left(1-\frac{r^2}{a^2}\right)}{ar}\left\{\frac{1}{\left(1+\frac{2r}{a}\cos. u+\frac{r^2}{a^2}\right)^{\frac{3}{2}}}-\frac{1}{\left(1-\frac{2r}{a}\cos. u+\frac{r^2}{a^2}\right)^{\frac{3}{2}}}\right\}$$

Since we suppose the two spheres very distant from each other, compared with the magnitude of their radii, $\frac{r}{a}$ will be a very small fraction; hence we may develope this expression for E—E into a converging series of the ascending powers of $\frac{r}{a}$, this will be effected by the binomial theorem; and taking only the first power of $\frac{r}{a}$, which, in the case we are considering, will contain an infinitely great proportion of the total result, compared with the other powers, it will become

$$E-E=\frac{e'r'^2}{ar}\left\{1-\frac{3r}{a}\cos. u-1-\frac{3r}{a}\cos. u\right\}$$

or by reduction $E-E_{,}=-6r'^2e'\cos. u.$

This value of $E-E_{,}$ must now be multiplied by $E+E_{,}$ to form the factor $E^2-E_{,}^2$ which enters into the expression of the total resulting force; but since $E-E_{,}$ is already of the order $\frac{r'^2}{a^2}$ it is evident that, in $E+E_{,}$ we must confine ourselves to the terms which are not divided by a; this limitation reduces the value of $E+E_{,}$ to $2e$, and employing this to multiply $E-E_{,}$ there results

$$E^2-E_{,}^2=\frac{-12ee'r'^2}{a^2}\cos. u.$$

It only remains to substitute this value in the expression of the resulting force, parallel to the co-ordinates x, which we have found equal to $\frac{Kx\varpi}{r}(E^2-E_{,}^2)$ for the superficial element ϖ; and by putting for $\frac{x}{r}$ its value, $\cos. u$, the expression will become

$$\frac{-12Kee'r'^2}{a^2}\varpi\cos.^2 u.$$

Each of these partial results is proportional to the superficial element ϖ, and to the square of the cosine of the angle, which these elements form with the axis of the co-ordinates x. But, if we compare them together upon different spheres, this angle will always be expressed by the same values; for the equal values of u, however, the superficial element ϖ will vary in magnitude proportionally to the square of the radius r of the sphere. Consequently, the sum of all the values of the factor $\varpi\cos.^2 u$, extended to every sphere, will only vary from each other in the ratio of the square r^2; it may be represented then by $K'r^2$, K' being a constant and numerical co-efficient which may be found, and which, in reality, is found by the processes of the integral calculus. Supposing it known then, the total result of the pressures parallel to the co-ordinates x will be $\frac{-12KK'ee'r^2r'^2}{a^2}$ (1).

It will be directly proportional then to the quantities $4\pi^2r^2e$, $4\pi r'^2e'$ of external electricity which they possess, and inversely proportional to the square of the distance of the two centres. When the quantities of electricity given to the two spheres are of the same nature, whether vitreous or resinous, the values of e and of e' must be considered as having the same sign. In that case the expression (1) is negative, that is to say, according to what has been previously admitted, that, in this case, the air which surrounds the sphere

A, is more pressed in the direction BA, than in the direction AB. It will not then press equally the sphere A, as it did before it was electrified; it will press it less on the side which is most distant from the other sphere, since it is in that direction that the electric reaction is the strongest. Consequently, if the sphere A is at liberty to move, and deprived of its weight, or if its weight be sustained by a thread of suspension, it will put itself in motion from the side where the atmospheric pressure has become the weakest, that is to say, that it will recede from the other sphere B.

The contrary would happen, according to our formula, if the quantities e,e' of electricity introduced into the two spheres were of a different nature, for then it would be necessary in the calculation to give to them different signs. The formula (1), which represents the total result of the pressures exerted against the air parallel to the line of the centres, will then become positive, that is to say, according to what has been already agreed on, the external air will be more pressed in the direction AB, than in that of BA; the sphere A will move then in the direction in which the external pressure will have become the weakest, that is towards the sphere B, agreeably to observation.

We have hitherto only considered the effect of the pressures round the sphere A, but the same reasonings and calculations will apply to the other sphere; only we must then employ, instead of E and $E_{,}$ the expressions of the electric strata which correspond to them, and which we have seen to be

$$E' = e' - \frac{3er^2}{a^2}\cos. u' + \frac{5er^2r'}{2a^3}(1 - 3\cos.^2 u').$$

It might be shown for this case, as well as for the other, that there cannot be any inequality of pressure but in the direction of the co-ordinates x; then comparing the points of the surface which correspond to the two sides of the plane of the co-ordinates $y\,z$, we shall find that the element of the resulting force of the pressures parallel to the co-ordinates x, is in general expressed by $\frac{Kx\omega^4}{r'}(E'^2 - E_{,}'^2)$ in representing by $E_{,}'$ what E' becomes when we change $+x$ into $-x$, that is to say, $+\cos. u'$ into $-\cos. u'$, the angle u' being here reckoned from the point a, situated on the side of A upon the line of the centres. By next considering the spheres as very distant we will obtain in the same manner the value of $E' - E_{,}'$. Approximating no farther than the first power of $\frac{r'}{a}$, this will give $E' - E_{,}' = \frac{-6er^2}{a^2}\cos. u'$. We have then only to take $E + E_{,}' = 2e'$, and putting these values in the expressions of the partial resulting force, it will become $\frac{-12Kee'r^2\omega'\cos.^2 u'}{a^2}$. It may be demonstrated as above, that the sum of the factors $\omega'\cos.^2 u'$ will be proportional to the square of the radius of the sphere B, and may besides be represented by $K'r'^2$; K′ being the same numerical coefficient we have already employed. For the total resulting force then, the expression will finally become $\frac{-12KK'ee'r^2r'^2}{a^2}$, that is, exactly the same which we have obtained for the other sphere, which ought to be the case, since in these sort of phenomena action and reaction are always equal. Here, as in the example immediately above, the positive sign of the expression will signify that the resulting force of the pressures exerted against the air round the sphere B, is directed towards the other sphere, and the negative sign will signify that this resulting force is directed the opposite way. The first case will take place when the electric charges ee' are of a contrary nature; in that case, the sphere B will advance from the side where the atmospheric pressure is weakest, that is towards A; the other case will happen when the electric charges ee' are of the same nature, then B will recede from A.

The common expression for the result of the pressures vanishes for both the spheres, when e or e' is nothing, that is, when one of them is in the natural state. This seems to indicate that they would then neither approach nor recede from each other, while, in reality, we know that in this case they always approach. This apparent contradiction is owing to the degree of approximation at which we stopped our developement of the above expression. We have supposed our two spheres very distant from each other, compared with the radii of their surfaces; the result of this is, that whatever be the quantity $4\pi r^2e$, $4\pi r'^2e'$ of external electricity which we have introduced into each of them, it will distribute itself almost uniformly over the two hemispheres, anterior and posterior; so that the difference of the pressures exerted against the air by these two hemispheres, which is the only cause of motion, will be very small, and it is to this degree of minuteness that we have confined our approximations in developing $E^2 - E'^2$.

If, however, the one of the two spheres, B for example, is only electrified by the influence of the other, which we always suppose very distant, the developement of its natural electricities will be still very feeble, and of the same order of minuteness with that to which we have confined our approximations; but this weak electricity still dividing itself between the two hemispheres of B, in a manner nearly equal, as in the example immediately above, the difference of pressures round the two hemispheres will become very minute in a still lower degree—will become a quantity of the second order of minuteness, and, consequently, cannot be found in our developements, such as we have limited them. To obtain it complete, we must not, in the calculation of $E' + E_{,}'$ confine ourselves to quantities, independent of $\frac{r'}{a}$, but take its whole value. We will then have, first of all,

$$E' = e' - \frac{3e\,r^2}{a^2}\cos. u' + \frac{5e\,r^2\,r'}{2\,a^3}(1 - 3\cos.^2 u')$$

then changing $+x$ into $-x$, or $+\cos. u'$ into $-\cos. u$, we will have,

$$E_{,}' = e' + \frac{3er^2 \cos. u'}{a^3} + \frac{5er^2r'}{2a^3}(1 - 3\cos.^2 u')$$

then adding these two expressions,

$$E' + E_{,}' = 2e' + \frac{5er^2r'}{a^3}(1 - 3\cos.^2 u')$$

This complete value of $E' + E_{,}'$ will now no more vanish when e' is nothing, but it will be seen that the terms which remain are of the order of those which we have neglected in our first approximation. Making, then, here e' equal to nothing, it remains,

$$E' + E_{,}' = \frac{5er^2r'}{a^3}(1 - 3\cos.^2 u')$$

we also find, as before,

$$E' - E_{,}' = -\frac{6er^2}{a^2}\cos. u'$$

with these values, the expression of the partial resulting force $\frac{K\,x\,\omega'}{r'}(E'^2 - E_{,}'^2)$, or $K\,\omega'(E'^2 - E_{,}'^2)\cos. u'$ becomes $-30Ke^2r^4r' . \omega' \cos.^2 u'(1 - 3\cos.^2 u')$.

It only remains to take the sum of it over all the extent of the surface of the sphere B; but, in this operation, the variable factor, $\omega' \cos.^2 u'(1 - 3\cos.^2 u')$, will give a result proportional to the square of the radius r' of the sphere B, and which we may consequently represent by $K'' r'^2$, K'' being a constant numerical co-efficient different from K'; thus, the total resulting force will at last be

$$\frac{-30KK''e^2r^4r'^3}{a^5}.$$

This force, then, will be of an order of minuteness, much inferior to that which we obtained at first, when e' was not supposed to be nothing, since the radii there are divided by the fifth power of the distance of the centres of the two spheres, instead of the simple square which we had in the other approximation. It is obvious, that experiments of this kind, made with the electric balance, by charging only one of the balls, might produce an error as to the true law of the phenomena, if the theory did not throw light upon them; for one might be led to conclude from them, that the apparent attraction determined in this case is not reciprocally as the square of the distance of the centres of the two spheres, which nevertheless would be contrary to the truth; consequently, when it is meant to put this simple law of the square to the test, the balls must not be allowed to approach so near to each other, that the electricity developed by their reciprocal influence may bear any sensible proportion to the quantities of external electricity introduced into them; and this is the reason, that, in these experiments, it is always more certain to employ, instead of balls, small circular disks of gilt paper; for, on account of the thinness of these disks, the quantities of vitreous or resinous electricity developed at their surfaces, having nearly no room to separate from each other, their actions on the exterior bodies must be always about exactly alike, and cannot, therefore, alter the results any more than if their developement had not taken place.

The theory, which we have thus explained in regard to spheres, applies equally well to bodies of any form whatever; but here the difficulty of the analysis prevents us from anticipating any thing but the general effects which the different pressures produce, without our being able to reduce them to numbers. Those who wish to enter into the details, will find them in Biot's *Physique Mathematique*, Tom. II. Here it will suffice to have established the general mode of reasoning applicable to all the questions of this kind, and to have followed out the whole developement for the single case, which analysis has been able as yet completely to surmount. We shall add, that before the theory had acquired its actual precision, it could not be clearly conceived how the attractions and repulsions, which in reality only take place between the electrical principles themselves, were communicated to the material particles of the electrified bodies; and philosophers were reduced to the necessity of denoting this effect by the vague word *tension*, which represented the electricity like a kind of spring placed between the bodies, and tending to make them approach or recede.

In the preceding observations, we have only attended to the statics and the dynamics of electricity, that is, to the laws of its equilibrium and of its motion. To complete these additions, it would be necessary still to consider its chemical action, concerning which many discoveries have also been made since the publication of the *Encyclopædia;* but it will be better to place these results under the article GALVANISM, as they will there be united with a great number of others, which will mutually throw light upon each other, and at the same time will render more certain, and more general, the theoretical consequences which may be drawn from them. We shall only present here some necessary modifications of the ideas which may be formed from the *Encyclopædia*, in regard to the nature of the two electricities, and to the physical impressions by which their material existence seems to become manifest to our senses. The light which the electric spark excites in the air, does not by any means prove that the electric principle itself is luminous, any more than the phosphoric odour, which the electrified points produce on the organ of smell, prove that this principle is odorous. It is now known by experiment, that every sudden stroke, every rapid motion, impressed on a mass of air, which cannot yield with sufficient agility, excites in it a degree of light; and, in order that it may thus be excited in the open air, it is sufficient that it be impelled more vigorously than its own resistance permits it to give way. Whatever may be the nature of electricity, we know that it produces upon bodies in which it is contained, and on those which it traverses, a repulsive force, which becomes, in many instances, extremely energetic. We know, besides, that, without any estimable mass for our most sensible balances, it may yet impress upon these bodies very rapid motions, when we accumulate it, and dispose it in such a manner, that the pressures which it exerts against the air around these bodies cannot mutually balance each other. Hence we may conclude, by the laws of mechanics, that the velocity of its transmission must be immense; but with an excessive velocity, and a very great repulsive force, what more is wanting to compress the air, and even the rarest vapours, even to the point where the disengagement of light begins? This idea, which we believe was first proposed by M. Biot (*Annales de Chimie*, 1805, Tom. LIII. p. 321), seems to us to give a very plausible reason for these phenomena; and the possibility of so simple an explanation, is enough for authorizing us to reject as hypothetical the conclusion which has been too often drawn from this phenomenon, that the electric principle is heat, or a modification of heat. There is still less occasion to insist on the uncertainty of that other hypothetical conclusion, that the electric principle is odorous. Whenever it is discovered that this principle may occasion mechanical motions in lifeless bodies, and that its rapid transmission may excite muscular contractions in organised bodies, by a moment's reflection we can conceive that the same influence may excite tickling in the pituitary membrane, in such a manner as to produce in us a sensation like what the impression of a body really odorous may occasion. These phenomena, then, are not characters peculiar to the electric principles, and essential to their existence; they are very probably simple modifications which its repulsive force produces in bodies, or in us. We may venture to add, that they do not prove even its materiality; for what proof is there, that a repulsive force cannot be excited, or arise in any point of space, without being attached to sensible and ponderable particles? The only strong induction, the only one perhaps of really any weight as to the materiality of the electric principles, is, that in all the phenomena of their equilibrium and motions, they act exactly as two fluids would do, whose particles would mutually repel each other, and attract those of the other fluid reciprocally as the squares of the distances. This constitution being supposed, all the electrical phenomena become the rigorous mechanical consequences of it; can be anticipated with the most perfect precision, and can even be reduced to numbers in their minutest details, as well as in their most intricate windings, when the analysis may apply to them. Does not this, then, afford a very strong presumption, that these two principles are in effect and in *reality* such as this constitution, deduced from the phenomena, indicates?

Finally, Whatever the true nature of electricity may be, in itself, since the constitution which we have ascribed to the two electric fluids reproduces exactly and numerically all the phenomena, which as yet it has been possible to develope by calculus, this is enough to entitle us to admit this constitution in our farther inquiries. For we are authorized to conclude, from the verifications already established, that the real nature of electricity, whatever it may be, must conform itself to the facts with equal exactness; and, on the other hand, that, when applied to these facts, it will reduce itself to the same conditions which we have attributed to the two fluids; so that the facts will not flow from it otherwise, nor by other formulas, than what we now employ. But new observations, and even new applications, will serve, when the mathematical analysis will have become more perfect, to confirm or destroy the physical reality of the theory, and will show whether it is an exact and general interpretation of all the phenomena, or whether only an approximate and particular expression of those which till now it has embraced.

This progression of ideas may be already observed in the succession of the theories anterior to this, which we have here explained. And among these speculations one has been too justly celebrated, and too useful, to be passed over in silence. Most of the electric phenomena, if we look only to their general circumstances, may be represented, by supposing only the existence of a single electric fluid, of which a certain quantity is diffused through all bodies, and forms their natural state. The excess of this fluid in bodies produces what we have called the vitreous electricity; its deficiency what we have called the resinous electricity. Hence arise two states of the bodies, which the followers of this system denote by the terms *positive* and *negative*. They admit, also, that the particles of the electric fluid mutually repel each other; but as experience shows, that bodies in the natural state do not exert any action on each other, they are besides constrained to suppose, that the electric particles are attracted by the matter itself of the bodies; and lastly, as it is proved by a profound discussion and calculation, that even this condition will not be sufficient to establish the equilibrium, it becomes necessary farther to admit, that the particles of all bodies exert on each other a repulsive action, sensible, like the electric influences themselves, at great distances, and varying according to the same laws with the distance. Franklin, who first imagined this system, and who employed it ingeniously to unite all the electric phenomena known in his time, and which till then were scattered and unconnected together,—Franklin did not perceive the consequence to which his hypothesis led. Æpinus was the first who, by an exact analysis of all the forces by which the electric equilibrium was brought about, discovered the necessity of a repulsion between the particles of the bodies (*Tentamen Theoriæ Electricitatis et Magnetismi*, p. 39), and, after him, the celebrated philosopher Henry Cavendish was led to the same consequence; for he made this repulsion one of the fundamental conditions of his hypothesis on the nature of electricity, published in the *Philosophical Transactions* for the year 1771, and which accords exactly with the hypothesis of Æpinus.

Although the existence of such a repulsive force between material particles of all bodies may, at first view, seem quite opposite to the general phenomena of the universe, particularly to the great law of celestial attraction, it is not so in fact; for this repulsion, as it is employed by Æpinus and Cavendish, would be exactly balanced by the mutual attraction which the hypothesis supposes to exist between the electric fluid and all material substances, when they are in their natural state of electricity; so that no resulting force would be exerted in this state by their mutual actions; and then, all other properties, or forces emanating from the bodies, as attraction seems to be one, could equally exist and manifest their power in the state of electrical saturation, as well as if there existed no repulsive action whatever between the matter of bodies. In effect, if we admit such a state of things, we may connect together by it a great number of electric phenomena, conceive their mutual dependence, and anticipate them, not, indeed, as to the quantity and number, but in their general circumstances. This view of the subject is fully discussed in the *Encyclopædia*, where the results of this system are explained in detail. We thus explain, for example, the attractions and repulsions of electrified bodies, and even the developement of electric properties in bodies, in the natural state, by the sole influence at a distance of an electrified body. But, from the time when this theory was first imagined, many circumstances of the phenomena have been more accurately, and more precisely fixed, and many have been limited by exact measurements. In fine, we know them by numbers; and it is in number that the theory must now represent them. When Æpinus and Cavendish wrote, the law of electric attractions and repulsions was not yet ascertained by experiment. It could be doubted, then, whether these forces varied according to the cube, to the square, or to some other power of the distances; and it was consequently impossible to compute numerically the distribution of electricity in the bodies where it disposes itself by its proper equilibrium, or to assign the proportion of its allotment between two bodies of a given form, since these delicate effects are dependent on the laws by which the action of the fluid upon itself and other bodies is regulated. In the law of the cube, for example, the distribution and the division of electricity would be different from what they are in the law of the square, and the former may be now rejected, as giving consequences contrary to actual observation. In like manner, if we now introduce the law of the square in Æpinus's or Cavendish's hypothesis, we would probably be led to consequences which would be found inconsistent with the exact measurement of these phenomena which we now possess; but this deduction has not yet been made, and seems very difficult to be done. Happily it does not now appear to be of any importance, since the hypothesis so pursued could have no greater success than to agree with the facts, which the theory of the two fluids already does in the most exact manner, and what is of no small consideration, with a complete evidence, simplicity, and facility to be expressed by analysis. (z. z.)

ELLIPTIC TURNING. Wood and other substances are turned into an elliptic form by means of a chuck, which is applied on the common turning lathe. This chuck is on the principle of the trammel, Plate LXXIX. fig. 1. The grooves in the chuck are much wider than in the trammel, and the points of the chuck that correspond to C, D, of the trammel, fig. 1, remain fixed, and in one horizontal line, whereas in the trammel it is these points that are put in motion.

Illustration of the Principle.

If two straight lines, crossing each other, be drawn on a piece of transparent paper or mica; and if this transparent paper be laid upon a sheet of white paper, with two points marked on it; and if the transparent paper be moved round, so that the cross lines shall travel over the two points, in like manner as the two points, C, D, in the trammel, fig. 1, travel over the cross grooves of the trammel; and if the point of a pencil be held fixed, and touching the transparent paper, so as to leave a trace on the transparent paper, when the paper is moved; then after the transparent paper has made a revolution, the trace left on it by the point of the pencil is an ellipse. This method of describing an ellipse represents the action that takes place in the chuck for turning ellipses; the point of the pencil which remains unmoved is in the same situation as the turner's gouge; the transparent paper, which receives the trace of the ellipse from the fixed pencil is analogous to the wood, which is to be turned into the form of an ellipse by the fixed cutting gouge.

Description of the Chuck.

In fig. 2, the chuck is represented as fitted on a common turning lathe, of which A is the pulley of the maundrel, B and C are the sides of the frame supporting the pulley, P the rest, D the frame in which the rest slides, E F the feet of that frame, I the nut and screw which serve to fix the rest, G H are the continuation of the sides B C. K is the elliptic chuck, with two grooves, through which the knobs of the slider pass; these knobs are connected by a strong bar of iron screwed into their ends, and on this bar of iron is seen the screw for fastening the board, to which is fixed the wood or other substance which is to be turned elliptically.

Fig. 3. shows the other side of the chuck, which, in fig. 2, is turned towards the side of the frame C. N, in fig. 3, is the board with the grooves, which contain the slider O. In the middle of N is seen the end of the screw, which is fixed to the maundrel. The board N has a circular motion, being fixed on the axis of the maundrel, whilst the slider O, at the same time that it is carried round by the circular motion of N, is constrained to perform other motions by the grooves in N, and by the groove in O, fig. 3, which slides on the ring M, fig. 4.

In fig. 4. L is a part of the side C of the maundrel frame, with the ring M fastened to it. On this ring, the broad groove in the slider O, fig. 3, moves when the lathe is set a going; and this groove is at right-angles to the grooves in N, fig. 3, in which the knobs of O move. In fig. 4, it is seen that the centre of the ring M may be made to coincide with the centre of the spindle of the maundrel, in which case a circle is described. If the ring is fixed, so that the centre of the ring does not coincide with the centre of the maundrel, an ellipse is described by the wood screwed upon the bar of O, in fig. 2; and the most eccentric ellipse that the machine describes is obtained, when the maundrel is at the circumference of the ring. The centre of the spindle of the maundrel, and the centre of the ring M, are always in one immoveable horizontal line, and are analagous to the points C, D, of the trammel, fig. 1. In fig. 3, it is seen that the sides of the grooves may be brought nearer together by means of screws, so that the sliders and the cylindric ring may fit exactly to the grooves. The best elliptic chucks are made of brass. See *Mechanical Exercises*, by Peter Nicholson, London, 1812. (Y.)

ELLIPTOGRAPH, an instrument for drawing ellipses. The trammel is an instrument that has long been known and used for describing ellipses. On the principle of the trammel, Mr Farey constructed his elliptograph in a form much more commodious for drawing. Mr Farey's elliptograph is represented at fig. 5, Plate LXXIX. The circle A slides between the two parallel rulers D E. The circle B slides between two parallel rulers F G, at right angles to the former. In this way, if a line, joining the centres of the circles, is made to revolve, M, the extremity of that line, will describe an ellipse in the same manner, as the extremity E of the line C D E, fig. 1, does in the trammel. The elliptograph may be considered as a trammel, in which the pins C and D, fig. 1, are enlarged into the circles A and B, *fig. 5.* The pinion at K, fixed to one of the arms of the lower circle, acting on a rack screwed to the upper circle, serves to alter the distance of the centres of the circles A and B, and, by so doing, this pinion serves to vary the eccentricity of the ellipses which the instrument describes. When the centres of the circles A B coincide, the describing pen M draws a circle. When the centres are removed from each other, and on the circles being turned round, an ellipse is described by the pen; and when the distance of the centres is increased, the eccentricity of the ellipse is increased. When the pen is at the centre it describes a straight line, continually moving to and fro on that line when the circles are turned round. The two circles are fixed together by screws, and can only be made to slide the upper circle over the lower by the action of the pinion K. The pinion at L moves a rack, by which the describing pen M, which draws the ellipse, is brought nearer to the centre, for the purpose of drawing a small ellipse; and removed farther from the centre of the ellipse, when a large one is to be drawn. The size of the ellipse may be increased as far as the size of the instrument will admit. The pair of rulers D E are placed below the pair F G, as is seen in fig. 6. The instrument, when used, is held upon the paper with the thumb and a finger of the left hand at the nuts N O, and the circles are moved by applying the right hand to the pins *f*, the pen M, pressing by its weight on the paper, then describes the ellipse.

Fig. 7 shows H the socket for the compasses, with the centre pin on which the socket moves; and the pinion L and rack *h* for moving along the frame *g* between the bars; and the other pinion K for separating the circles.

The ruler P has two points to fix the instrument to the paper. The ruler is united to the frame by screws, which serve to adjust the position of the instrument after the ruler has been fixed to the paper.

Mode of using the Instrument.

By means of the elliptograph, any ellipse can be described, of which the long and short axis are given, provided it does not exceed the size of the instrument. When an ellipse is to be described, draw on the paper the longer and shorter axis, bisecting each other; place the instrument on the paper so that the centre of the four rulers appears to coincide with the centre or the intersection of the two axes of the ellipse; fix the instrument in this situation by the points that go into the paper: by the pinion L move the pen to one extremity of the short axis of the ellipse; turn the circles half round to see if the pen comes to the other end of the short axis; if it does not, adjust the error one-half, by moving the pen by the pinion L, the other half by moving the frame on the paper; continue this adjustment till the pen, setting out from the one end of the short axis, arrives in a half revolution at the other end. Next, by means of the pinion K, bring the pen to one end of the long axis of the ellipse; turn the circles half round, and if the pen reaches the other extremity of the long axis of the ellipse, the instrument is rectified: if not, one-half of the error is to be corrected by moving the circles by the pinion K, and the other half by moving the instrument to a side on the paper by means of the nuts N, O. The instrument is now adjusted, and the pen resting on the paper traces the ellipse required when the circles are turned round by the handles.

Elliptograph for Engraving.

An instrument similar to the elliptograph has been employed for engraving ellipses on copper plates, and for dividing these ellipses accurately, so as to give the perspective representation of a circle divided into equal parts, both in the case where the distance of the eye is limited, and in the orthographic projection. The *Society for Encouraging Arts* rewarded Mr Farey with their gold medal for his invention, and a description of the elliptograph is contained in the thirty-first volume of the *Transactions* of that Society. (Y.)

EMBANKMENT, a mound, or wall of earth, or other materials, used as a defence against the inundations of rivers, or the extraordinary flux of the sea.

The great value of alluvial soil to the agriculturist, no doubt, gave rise to the invention of banks, or other barriers, to protect such soils from the overflowing of their accompanying rivers. The civilized nations of the highest antiquity were chiefly inhabitants of vallies and alluvial plains; the soil, moisture, and warmth of which, by enlarging the parts, and ameliorating the fruits of the vegetable kingdom, afforded to man better nourishment, at less labour, than could be obtained in hilly districts. The country of Paradise, and around Babylon, was flat, and the soil a saponaceous clay, occasionally overflown by the Euphrates. The inhabited part of Egypt was also entirely of this description. Historians inform us, that embankments were first used by the Babylonians and Egyptians, very little by the Greeks, and a good deal by the Romans, who embanked the Tiber near Rome, and the Po for many stadia from its embouchure. The latter is perhaps one of the most singular cases of embankment in the world.

The oldest embankment in England is that of Romney Marsh, as to the origin of which, Dugdale remarks: "that there is no testimony left *to us* from any record or historian." *(History of Embanking and Draining.)* It is conjectured to have been the work the Romans, as well as the banks on each side of the Thames, for several miles above London, which protect from floods and spring tides, several thousand acres of the richest garden ground in the neighbourhood of the metropolis.

The commencement of modern embankments in England took place about the middle of the seventeenth century, under Cromwell. In the space of a few years previously to 1651, 425,000 acres of fens, morasses, or overflown muddy lands, were recovered in Lincolnshire, Cambridgeshire, Hampshire, and Kent; and let at from 2s. 6d. to 30s. an acre. (Harte's *Essays*, p. 54, 2d edit.) Vermuyden, a Fleming by birth, and a colonel of horse under Cromwell, who had served in Germany during the thirty years' war, was the principal undertaker of these works. The works of this sort constructed in our own times will be found described in the *Agricultural Reports* of the maritime counties, especially of Lincolnshire, by Arthur Young.

Previous to entering on the detail of the different descriptions of banks for the purpose of embanking, we shall here observe, that the pressure of still water against the sides of the vessel containing it, being as its depth, it follows, that a bank of any material whatever, impervious to water, whose section is a right angled triangle, and the height of whose perpendicular side is equal to that of the water it is to dam in, will balance or resist this water, whatever may be the breadth of the surface of the latter; and, therefore, that as far as width or extent is concerned, it is just as easy to exclude the Atlantic Ocean, as a lake or a river of a few yards in width.

The Earthen Wall.

1. THE EARTHEN WALL (fig. 1. Plate LXXIX.) is the simplest description of embankment, and is frequently erected by temporary occupiers of lands on the general principle of enclosing and subdividing, which is sometimes made a condition of tenure between the landlord and tenant. This wall applies to lands occasionally, but rarely overflown, or inundated; and is set out in a direction generally parallel to the river or shore. Its base is commenced on the surface from two to five feet wide, regularly built of turf on the outsides, with the grassy sides underneath. The middle of the wall is filled up with loose earth. The wall is carried up with the sides bevelled towards the centre, so as to finish in a width of one foot or eighteen inches at five or six feet in height. In the inside of such walls, and at the distance of three or four feet, a small open drain is formed, as well to collect the surface water of the grounds within, as that which, in time of floods, will necessarily oose through a wall of this construction. The water so collected is let through the wall by tubes, or tunnels of boards, with a valve opening outwards on their exterior extremity. Such a tube and valve is represented by fig. 2. When the flow of water from without approaches, it shuts the valve, which remains in this state till the flood subsides, when the height of the water within being greater than that without, it presses open the valve and escapes. Walls and valves of this kind were erected about the year 1800, on the estate of the Earl of Galloway near Wigton, by Mr Hannah, tenant for life of Cue farm; and by Mr Hutchinson, tenant for thirty years of Mersehead farm, on the Solway Frith. *(Farmer's Magazine.)* They are common enough in the drier parts of the fenny districts of Lincolnshire and Cambridgeshire; and in Caernarvonshire 1800 acres were, in 1804, completely protected in this way on the estate of Tre Madoc by the proprietor, who has since made greater efforts in embanking, to be afterwards described.

The Earthen Mound.

2. THE EARTHEN MOUND (fig. 3.) is the most general description of embankment, and as it is executed at considerable expence, is only undertaken by such as have a permanent interest in the soil. This barrier applies to sea lands overflown by every spring tide, and to alluvial plains inundated by every flood. It is set out in a direction parallel to the shore, and to the general turns of the river, but not to its minute windings; and it is placed farther from or nearer to the latter, according to the quantity of water in time of floods, the rapidity of the current from the declivity of the bed, the straight course of the stream, and the intended height of the bank. The two sides of such a mound are generally formed in different slopes. That towards the land is always the most abrupt, but can never be secure if more so than 45°; that towards the water varies from 45° to 15°; the power of the bank to resist the weight of the water, as well as to break its force when in motion, being inversely as its steepness. The power of water to lessen the gravity of bodies, or, in other words, to loosen the surfaces over which they flow or stand, is also lessened in a ratio somewhat similar.

The formation of such a mound consists merely in taking earth from the general surface of the ground to be protected, or from a collateral excavation, distant at least the width of the mound from its base line, and heaping it up in the desired form. The surface is then in general cases covered with turf, well rolled in order to bind it to the loose earth. The earth of such mounds is generally wheeled by barrows; but sometimes it is led by carts placed on a wooden roller instead of wheels, which, with the treading of the horses, serves in some degree to consolidate the bank.

The excavation within serves the same purpose as the open drain in the *earthen wall*, and similarly constructed sluices or valves are introduced on a larger scale. Sometimes also the interior water is drawn off by windmills, and thrown over the mound into the river. This is very common in Huntingdonshire, and might be greatly improved on by employing steam-engines for entire districts, one of which, of a ten horse power, would do the work of twenty mills, and this in calm weather, when the latter cannot move.

Embankments of this description are the most universal of any, and their sections vary from a scalene triangle of ten feet in base, and three feet in height, as on the Forth near Stirling, and the Thames at Fulham, to a base of 100 feet, and a height of ten feet, as in the great bank of the Ouse, near Wisbeach. The great rivers of Germany and Holland are embanked in this way, when so far from the sea as to be out of the reach of the tide; as the Vistula at Marienwerder, the banks of which, near Dantzic, are above fifteen feet in height; the Oder, the Elbe, &c. All these banks are closely covered in every part with a grassy surface, and sometimes ornamented with rows of trees.

But, near the sea, where such banks are washed by every tide when the course of the wind is towards the shore, and by all land floods and spring-tides, grass is only to be found on and near their summits. The rest of the bank is bare, and to preserve it from the action of waves, currents, and the stones, pieces of wood, and other foreign matters which they carry with them, the surface is covered with gravel, reeds, or straw, kept down by pieces of wood; faggots, wicker hurdles, nets of straw-ropes, or any other contrivance, according to the situation, to prevent the washing away of the bank. It is common to attribute to these coverings the power of breaking the force of the waves; but this power depends, as we have already stated, on the slope of the bank and its smoothness; and the use of the surface covering, and of the constant attention required to remove all obstacles which may be left on it by floods and tides, is to prevent the loosening power of the water from wearing it into holes. For this purpose, a sheet of canvas or straw netting is as good, whilst it lasts, as a covering of plate-iron or stone pavement.

All banks whatever require to be constantly watched in time of floods or spring-tides, in order to remove every object, excepting sand or mud, which may be left by the water. Such objects, put in motion by the water, in a short time wear out large holes. These holes, presenting abrupt points to the stream, act as obstructions, soon become much larger, and if not immediately filled up, turfed over, and the turfs pinned down, or the new turfs rendered by some other means not easily softened and raised up by the water, will end in a breach of the bank. A similar effect is produced by a surface formed of unequal degrees of hardness and durability. The banks of this description in Holland, at Cuxhaven, and along the coast of Lincolnshire, are regularly watched throughout the year; the surface protection is repaired whenever it goes out of repair, as is the body of the bank in the summer season.

Varieties of the Mound.

Mound with Puddle-Wall.—It generally happens that the earth of such banks is alluvial, and their foundation of the same description; but there are some cases where the basis is sand, silt, or gravel; or a mud or black earth, as in some parts of Cambridgeshire and Lincolnshire, which does not easily become so compact. Here it is common, before beginning the bank, to bring up what is called a puddle ditch, or section of clay, in the centre of the highest part of the mound in the direction of its length, and of three or five feet wide, according to the depth of the silt and the intended height of the bank. When the clay of this puddle-ditch is well worked, either by men's feet or clay rammers, the bank will be perfectly impervious to water, and if against a mild stream or shore, need not contain such an accumulation of earth as where the imperviousness of the bank to water depends chiefly on the mass of materials. An important point to attend to in this variety of mound is, to found the section, or wall of clay, so deep as to be in contact with a stratum either by induration, or its argillaceous nature, impervious to water.

Mounds with reversed slopes, (fig. 4.)—In some cases of embanking rivers, as where they pass through parks, it is desirable to conceal, as much as possible, the appearance of a bank from the protected grounds, less able to break the force of waves. Here the mound is simply reversed, the steepest side being placed next the water. It is proper to observe, that such banks are not so strong by the difference of the weight of the triangle of water which would rest on the prolonged slope, were it placed next the river, and are more liable to be deranged in surface in proportion to the difference of the slopes.

Mound faced with stones.—This is the same species of mound, with a slope next the water of forty-five or fifty degrees, paved or causewayed with stones or timber. In Holland this pavement or causeway is often formed of planking or bricks; but in England generally with stones, and the mortar used is either some cement which will set under water, or, what is better, plants of moss firmly rammed between them. The objection to such banks are their expence, and their liability to be undermined invisibly by the admission of the water through crevices, &c. They are, therefore, chiefly used where there is little room, or where it is desirable to narrow and deepen the course of a river.

Mound protected by a wicker hedge.—This is a Dutch practice, and, where appearance is no object, has the advantage of not requiring watching. Wicker-work, however, subjected to the strain of waves, will be obviously less durable than where it lies flat on the ground, and can only decay chemically. This wicker hedge is sometimes a series of hurdles supported by posts and struts; but generally in Britain it is a dead hedge or row of stalks wattled or wrought with bushes presenting their spray to the sea or river. Besides placing such a hedge before a bank, others are sometimes placed in parallel rows on its surface; the object of which is to entrap sand, shells, and sea-weeds, to increase the mass of mound, or to collect shells for the purpose of carrying away as manure.

The sea wall (fig. 5.) is an embankment formed to protect abrupt and earthy shores or banks of rivers, and consists of a wall, varying in thickness, and in the inclination of its surface, according to the required height and other circumstances. Belidor in his *Traité de Hydraulique*, has given the exact curve which the section of such a wall ought to have, in order to resist loose earth, and which is somewhat greater than what we have given in the figure referred to, where the earth behind the wall is supposed to be chiefly firm. Some fine examples of such walls, for other purposes, occur in the CALEDONIAN CANAL, and perhaps the finest in the world are the granite walls which embank the Neva at Petersburg, the construction of which may serve as an example of a river case with a foundation of soft bog earth. A space of the river, say 100 feet long, and 20 wide along shore, being inclosed by a double row of piles, and filled in with loam in the usual way, the water is pumped out, and the ground excavated about ten feet deeper than the margin of the bed of the river. Poles are then inserted nearly as close as they can be put in, and driven to their full length. When finished this foundation occupies a breadth of from 12 to 18 feet, generally 15. The tops of the piles are now cut level, and covered with planks, and on this is raised a mass of brick-work for five or six feet, sloping on both sides as it ascends towards the centre line of the wall. In the course of rising six or seven feet, it is narrowed to five feet, and is within five feet of the bed of the margin of the river. Here the granite facing begins in immense blocks, and is continued at a slope of 15° from the perpendicular till it reaches the surface of the intended pathway. Here the wall from three feet is narrowed to an upright parapet, eighteen inches wide; and at four feet of height it is finished in a projecting coping of Finnish granite. The voids on each side of the wall are now filled with earth, the pavement on the land side (generally narrow) completed, and the piles removed, and another length taken in to repeat the operation.

There is another mode, adopted in Petersburg, of building under water by driving the piles and cutting them over level with a machine, and then sinking caissons of brick-work. This mode, however, is unsuitable for sea walls in general, which ought to be founded as deep as possible, and, at all events, under the bed of the water. The motion of the Neva is so slow as hardly to render this worth attending to.

In Britain, such walls are fortunately rare; for in proportion as it is agreeable and flattering to self-love to protect or gain lands never before cultivated, it must be mortifying to be obliged to protect such as have long been subjected to agriculture, and where success can only be said to have a negative advantage.

Embankments for fixing Drifting-sands, Shells, or Mud.—In several tracks of coast, the sea at ordinary tides barely covers a surface of sand; and these sands in dry weather, during high winds, are drifted and blown about in all directions. Great part of the north shores of the Solway Frith, of Lancaster Bay, and of the coast of Norfolk, is of this description. Mr Young, in his *Farmer's Letters*, informs us, that a considerable part of the county of Norfolk was drift-sand, even as far inland as Brandon in Suffolk, before the introduction of the turnip culture; and Harte (*Essay I.*) states, that some of what is now the richest land in Holland, was, about the middle of the sixteenth century, of this description. The suggestion of any mode, therefore, by which, at a moderate expence, such tracks could be fixed, and covered with vegetation, must be deemed worthy of a place in this article.

The mode which nature herself employs is as follows: After the tides and wind have raised a marginal strip of sand as high as high water mark, it becomes by degrees covered with vegetation, and chiefly by the *Elymus arenarius, Triticum junceum,* various species of *Juncus*, and sometimes by the *Galium verum*. With the exception of the first of these plants (the leaves and stalks of which are manufactured into mats and ropes in Anglesea, and the grain of which is ground and used as meal in Ireland), they are of no other use than fixing the sands, which, being composed in great part of the debris of shells expand as they decay, and contribute to raising the surface still higher, when the fibrous roots of good grasses soon destroy the others.

To assist nature in fixing drift-sands, it is only necessary to transplant the *Elymus*, which is to be had in abundance in almost every sandy coast in Britain; and as it would be liable to be blown away with the sands, if merely inserted in the common way, it seems advisable to tie the plants to the upper ends of *willow* or *elder* rods, of two or three feet in length, and to insert these in the sand, by which means there is the double chance of the grass growing, and the truncheon taking root. The elder will grow exposed to the sea breeze, and no plant throws out so many and such vigorous roots in proportion to its shoots.

The mode by which such sands were fixed in Holland was by the formation of wicker work embankments, and by sticking in the sands branches of trees, bushes, furze, &c. in all directions. These obstructed the motion of the sands, and collected masses of sand, shells or mud, and sea-weeds around them, which were immediately planted with some description of creeping grass; or, what was more frequent, covered with a thin coating of clay, or alluvial earth, and sown with clover.

Though the most certain and least expensive mode of gaining such lands be undoubtedly that of seconding the efforts of nature, by inserting bushes, and planting the *Elymus* in this way, yet it may sometimes be desirable to make a grand effort to protect an extensive surface, by forming a bank of branches, which might, in a single or in several tides, be filled with sand and shells. It is evident, that such a bank might be constructed in various ways; but that which would be most certain of remaining firm, and effecting the purpose, would be one regularly constructed of framed timber, the section of which would resemble a trussed roof; each truss being joined in the direction of the bank by rafters, and the whole inside and surface stuck full of branches. To retain it firm, piles would require to be driven into the sand, to the upper parts of which would be attached the trusses. The height of such a barrier would require to be several feet above that of the highest spring-tides; and the more its width at base exceeded the proportion of that of an equilateral triangle the better.

A more economical mode, and one, therefore, suited to a less extensive scale of operation, is to intersect a sandy shore in all directions, with common dead, or wicker work hedges, formed by first driving a row of stakes six or eight feet into the ground, leaving their tops three or four feet above it, and then weaving among these stakes, branches of trees, or the tops of hedges. The Dutch are said to weave straw ropes, and thereby to collect mud in the manner of *warping*. This mode being little expensive, seems to deserve a trial in favourable situations; and, in so doing, it must not be forgotten, that much depends on the immediate management of the surface, after it is in some degree fixed. In an extensive trial of this sort at present in progress, on the west coast of Scotland, under an English gentleman, seeds and roots are baked in a mixture of loam and dung in the gravel, and then formed into masses, and scattered over a sandy surface. These, from their weight, will not, it is thought, be moved by the water or the wind; but becoming more or less covered with sand, the mass will be kept moist, and the seeds and roots will grow, and, fixing themselves in the soil, will in time cover the surface with verdure. The experiment is ingenious, and we hope will be crowned with success.

Embankments for straightening the Course of Rivers.—Where a river in a fertile valley is very circuitous in its course, land may be gained, and a more rapid efflux of the water produced, by straightening its course. The best plan in general for effecting this is, to find an entirely new bed or course for the river; otherwise, when it passes alternately through new soil, and through a part of its old bed, its action on surfaces which are so different in regard to induration ends, if great care is not taken, in holes and gulleys in the new bank, which require to be constantly filled up with loose stones thrown in, and left to be fixed by the pressure and motion of the water.

The embankment used in straightening the course of rivers is almost always the mound, with a clay wall in the centre, varying in width according to the depth of the different parts of the old bed of the river which it has to intersect. The materials for these banks are obtained from excavations for the new bed.

The pier, called the [illegible]g *Pier*, is to be considered as a species of em[illegible]t, whose object is to prevent the increase of partial breaches made in the banks of rivers, by accidental obstructions during floods. A tree or branch carried down by a stream, and deposited, or accidentally fixed or retained in its banks, will repel that part of the stream which strikes against it, and the impulse (counteracted more or less by the general current) will direct a substream against the opposite bank. The effect of this continual action against one point of the opposite bank is, to wear out a hole or breach; and the protecting pier is placed so as to receive the impulse of the substream, and reverberate it to the middle of the general stream. If this pier is not placed very obliquely to the substream, as well as to the general stream, it will prove injurious to the opposite bank, by directing a subcurrent there as great as the first; and, indeed, it is next to impossible to avoid this; so much so, that Mr Smeaton, in every instance in which he was consulted in cases of this sort, recommended removing the obstacle where that could be done, and then throwing loose stones into the breach. A perfect bed of a river would be a perfect half cylinder, and therefore we are decidedly of opinion that Mr Smeaton's mode is the best, as tending to maintain, as much as possible, this form. Mr Marshal (*Treatise on Landed Property*) has treated on piers of this description a considerable length; but a very little reflection will show, that they are more likely to increase than to remedy the evil they are intended to cure. We have seen the injurious effects of such piers on the Tay and the Dee, and on a part of the Jed near Crailing they are so numerous, that the stream is, to use a familiar phrase, banded about like a football, from one shore to the other; behind every pier an eddy is formed, and, if the stream does not strike it exactly, a breach in the bank. Many of these piers have, in consequence, been taken down.

The use of such piers can only be justified where the obstruction, from ill-neighbourhood or some such cause, cannot be removed from the opposite bank; or where, as is sometimes the case, it arises from an island of sand or gravel thrown out by the river near its middle, and which, however absurd it may appear, the interested parties cannot agree as to who may remove it. The case of buildings also being in danger may justify such a pier for immediate protection; but, if such breaches are taken in time, a few loads of loose stones will effect a remedy without the risk of incurring or occasioning a greater evil.

Such piers are frequently constructed of wicker work; either a mere wicker hedge projecting into the water, as is common where the rivers are of slow motion,—as in England, and particularly on the Thames, Tame, and Severn; or a case of wicker work filled with stones, as is common where the motion is rapid,—as in Scotland, and particularly on the Esk, Tweed, Tay, and Clyde.

Embankments to serve as Roads are generally mounds without clay walls, carried through countries liable to be overflown, without reference to protecting any part from water, through lakes or marshes, or across straits of the sea, &c. The earth, in such mounds, is generally allowed to take its own slope on both sides, which is commonly from 40° to 45°, and the width at top is regulated by that of the intended road. The materials, when the mound is formed in a country merely liable to be overflown, as in many parts of Lincolnshire and Huntingdonshire, are excavated from ditches, or taken from the surface on each side of the mound. In Holland, the roads formed on such mounds are bounded by rows of trees; a practice which, it is to be regretted, has not been more attended to in England, where accidents not unfrequently happen in the night, and particularly on the Boston and Wisebeach roads; both of which are formed in great part on such mounds, unprotected by hedges, rails, or trees. In passing through part of a lake, or strait, or marsh, the earth must, of course, be taken from the firm ground on the shores; and here the ground being generally soft below, the first operation is to lay a foundation, three or four feet thick, of branches or faggots of copsewood, in order that the mound may sink in a body. The next thing, the direction of the mound being marked out by a line of poles placed along its centre, is to begin at one end, and wheel, or cart on earth, throwing it down in the direction of the bank, and raising it to its proper height and width; leaving the slopes at the sides to

adjust themselves, either by the gravity of the material alone, or jointly with the loosening and spreading operation of the water.

The noblest attempt of this sort ever made in Britain was that of W. A. Madocks, Esq. M. P., to unite the counties of Merioneth and Cardigan by a mound across an estuary and embouchure of the Glasslyn two miles wide. Mr Madocks had, in 1802, succeeded in protecting from spring tides, by a wall or bank of the first species, 1800 acres of good alluvial soil, which he let at from 30s. to 50s. *per* acre; and his enterprising spirit induced him to contemplate the idea of gaining the whole bay or mouth of the stream, extending to nearly 4000 acres of alluvial and sandy earth, overflowed in great part by every tide. Besides the mere gaining of the land, this patriotic improver had another object in view; that of uniting two maritime points in two counties which at that time were separated by a day's journey; and, by effecting this, he would, at the same time, have rendered practicable a new line of road from Worcester along the top of this embankment, through a creation of his own, called the town of Tre Madoc, to the newly formed-harbour of Porthdynlleyn; by which 40 miles would have been saved to the public between Dublin and London, and 50 between Dublin and Bath, &c.

After consulting various engineers, the first operation was begun in 1807, and consisted in forming an immense bridge of flood-gates in the solid rock of the shore; as such a bridge and gates could not be formed in any part of the mound. The use of this was to admit the exit of the river. This done, the mound was commenced from both shores, and rocky, sandy, and clayey materials thrown down in the direction of the mound, and left to take their own slope. The greater part of these materials were argillaceous rock broken into small pieces, which being mixed with clay the mound would have been of the strongest texture. As the work proceeded, an iron rail-road was laid along the top of it, and extended to the quarries and excavations, by which means much labour was saved. In the course of three years the work was brought within fifty yards of meeting in the middle, but was found extremely difficult to close from the rapidity of the influx and reflux of the tide. This difficulty, however, would have been overcome, and the proposed improvement effected at little more than the estimated cost, L.20,000, had not the various and extensive projects in which the proprietor was at that time engaged, led him into pecuniary difficulties which put an end to the undertaking, and, as is usual in such cases, called forth popular clamour against the plan. It is but justice, however, to those concerned to state, that the very plan now put in execution was contemplated above a century ago by Sir Hugh Middleton, who then wrote to a friend, that, if he were not so deeply engaged in the scheme of bringing water to London, he should certainly engage in it.

Very little has been written on the subject of embankments, as a separate branch of art, by British authors. Dugdale's work is entirely historical and topographical. But the writings of Smeaton, Young, Gregory, &c. contain the general principles on which is founded the art of embanking, and every other operation connected with water.

(A.A.A.)

EMIGRATION.

The natural propensity of mankind is to settlement and rest, and this principle is still farther strengthened by the influence of local associations over the mind. Every one is strongly attached to the place of his birth, or to the place where he has passed his earlier years, and it may be generally remarked, that, in whatever spot man fixes his abode, there he takes root. Habits and sympathies are created, strong attachments are formed, and the longer he remains in any particular place, his aversion to change grows upon him. The power of early associations over the mind is exemplified by constant experience. How many of those adventurers who, at an early age, had quitted their home and their country in pursuit of fame or fortune, do we see daily returning to revive those local affections which, being deeply impressed on the heart while it was yet warm and susceptible, neither time nor distance has been able to efface? and to the powerful influence of the same tender recollections, are we to ascribe that painful longing and deep despondency to which the Swiss and other nations are liable when they have been long absent from their country and their home. Such being the general disposition of mankind to rest where their lot is cast—such the various and powerful ties by which they are attached to particular spots,—and so general their aversion to change, we may fairly conclude, when we see the inhabitants of any country eagerly engaging in projects of emigration, in opposition to their natural attachment to their native land, and in defiance of all the uncertainty and peril of a new settlement on a distant and unknown shore, that their conduct is not the result of choice but of necessity, and that, in thus leaving their kindred and their country, they are flying from the pressure of some great and general misery.

General View of the Subject as connected with the Principle of Population.

The great and radical evil which afflicts society is the want of food, which necessarily arises from the tendency of mankind to increase faster than the means of subsistence can be provided. The importance of this great law of nature, under which the want of food is every where found to be the great obstacle to the multiplication of the species, was first duly appreciated by Mr Malthus, who, in his profound and invaluable work *On Population*, has explained and enforced the principle with such elementary clearness and force, and with such various and striking illustrations, that it is now universally adopted as an indisputable maxim of political science.

According to the simple view of this interesting subject, contained in the work of Mr Malthus, it has been ascertained, from the history of the American and other newly settled colonies, that where there is abundance of food the population has been doubled in some cases in twenty-five, in others in fifteen years; and it is obvious that if 10,000, or any other number of inhabitants can be doubled within fifteen or twenty-five years, 20,000 or 100,000, or any greater number, may be doubled in the same period with equal facility. The increase of population takes place, therefore, according to a geometrical ratio; every successive addition affording the means of a still greater increase, until the earth being at length replenished with inhabitants, room and food are alike wanting for any farther addition to the human species.

It is not easy to determine the rate according to which the productions of the earth may be supposed to increase. This will in a great measure depend on accidental circumstances. Where there are extensive tracks of fertile and unoccupied land, food will be produced in great abundance; but after these are all cultivated, and the less fertile parts of the country begin to be settled by its increasing inhabitants, subsistence will be produced at a slower rate, and with greater toil. In this manner we find the population continues to advance according to an accelerated process, the increase of one period only affording the means of a still greater increase during the next, and this without any limit; while the subsistence for this rapidly increasing population, in place of being produced with the same facility, in place of increasing in proportion to the growing wants of the community, is necessarily produced at a slower rate, and with greater toil, at the period when it is most wanted. While the principle of population is yet in full vigour, and is every day acquiring new powers of increase, the produce of the earth is daily procured with greater difficulty. The same causes, therefore, which occasion a continual multiplication of inhabitants, prevent any progressive increase in the supply of provisions. By a long process of skilful cultivation, the earth may at last reach the utmost limits of its productive powers. This state of things, it is supposed, has already taken place in China. No efforts of human industry, however judiciously directed, could ever probably double the produce of this highly cultivated country. But the population could still be doubled in fifteen or twenty years with the same facility as before. All countries which have been long settled and cultivated, are in some measure in a similar condition. No efforts of human skill could possibly draw from Great Britain double its present produce within the period during which its population could be doubled, and in all such countries, therefore, the farther increase of inhabitants is checked by the want of food. It is manifest, indeed, that the number of people in any country, or in the world at large, must be limited by the quantity of subsistence provided for their support.

But though it is certain that the population of every country must be kept within the limits of its food, this object may be accomplished by the operation of two different causes. *1st*, General habits of refinement, or prudential motives, such as the fear of bringing children into existence without the means of supporting them, may so far operate on the minds of the labouring classes as to discourage marriage; in which case no superfluous inhabitants will be produced, and the supply of food, though it will admit of no increase, will still be sufficient for the maintenance of the population already in existence. Where the want of food operates in this manner to check the progress of population, Mr Malthus distinguishes it by the appellation of the *preventive* check. *2dly*, So strong, however, is the impulse by which man is prompted to multiply his species, that this preventive check seldom operates with sufficient force to restrain the undue increase of population. In all countries mankind have a perpetual tendency to increase faster than food can be provided, and even when the preventive check operates with most effect, the population frequently presses on the very verge of its subsistence; and is thus exposed, by an accidental failure in the ordinary supply of food, to all the miseries of want. As the number of inhabitants is necessarily restricted by the supply of subsistence, it is certain that, if the population increases beyond this limit, it will speedily be brought down to the level of its food by the operation of famine and disease, which Mr Malthus terms the *positive* in opposition to the *preventive* checks to population.

From this view then of the natural and immutable condition of human society, the want of subsistence seems to be a necessary and an inherent evil, under every form of it; to avoid which, mankind, as they begin to increase, are forced to separate in quest of new settlements, in which, the inhabitants being fewer, food is more easily procured. The want of subsistence is therefore the universal and constant cause of emigration, which forces mankind to disperse themselves, and to explore the world for a more desirable abode. It is no love of change or of adventure which prompts them to wander into unfrequented parts. It is the urgent pressure arising from an overcrowded population which impels them from their homes, which breaks the ties of kindred, and forces them to encounter all the hardships and dangers of new and untried scenes. Where a community is happy and prosperous, mankind will follow their natural propensity to settlement and rest; and it is only when this principle is disturbed by an opposite and equally powerful principle, namely, the fear or the actual experience of want, that emigration will be resorted to, as the least of two evils, not from choice but from necessity. It is under the influence of this great law of nature, namely, the tendency of mankind to increase faster than food can be provided for them, that the earth has been overspread with inhabitants. From the original seats of population and improvement, the human race would naturally overflow into other parts. The regions which were most desirable from their happier soil and climate would be first occupied; these being replenished with people, the overflowing stream would naturally reach the less habitable parts; until at length the frozen regions of the north and the burning climes of the south would be fully peopled, in proportion to the scanty subsistence to be drawn from them, by an unskilful and barbarous race.

The earth being in this manner filled with people, and no more vacant space remaining for new emigrations, the great check to population, from the want of subsistence, must now be felt in all its force; and it is evident that no farther increase of inhabitants can take place, unless new modes of subsistence be contrived, by which a greater supply of food may be derived from the same extent of territory. The most primitive and barbarous mode of life ever found to prevail among mankind, is, when they depend for subsistence on hunting and fishing, or on a casual supply of such produce as the earth spontaneously yields. From the humble and degraded condition of hunters, they gradually emerge into that of shepherds, and while their flocks and herds afford them a more certain provision, the care of these necessarily calls forth a greater degree of foresight than belongs to the hunting tribes, and the community being also in possession of a stock for their immediate subsistence, are, in every respect, in a superior condition to mere savages. It is in the agricultural state in which a community, adopting all the most ingenious and successful modes of cultivation, and improving, at the same time, in all the arts of commerce and industry, gradually accumulates capital and acquires habits of luxury and refinement, that the earth supports the greatest number of inhabitants, and to this state, therefore, mankind, impelled to improvement by the stimulus of necessity, continually tend. But as the course of improvement is retarded by a variety of causes, it has always happened that, in the general population of the world, three classes have been comprised, who, though variously modified, may be distinguished into those of hunters, shepherds, and agriculturists. When the earth is wholly occupied with these different communities, in each of which the population, according to the great law by which it increases, will soon reach the utmost limit of its food, it is manifest that the great standing cause of emigration will be in constant operation, and in this case there is little doubt that numbers will incur the risks of a removal for the sake of improving their condition.

The inhabitants of a country may emigrate individually, in which case they will be incorporated with the new community into which they enter, and their settlement will be made without violence; or a whole nation may emigrate, with a view of making their way to new settlements by the sword, and of driving out by force the inhabitants of the territory into which their irruption is made. Among civilized nations it is scarcely possible that this mode of emigration can take place. No government would countenance its subjects in any predatory irruption on the territory of another state; neither would the wealth acquired by civilized communities, nor the habits of order, industry, and peace, which wealth necessarily superinduces, at all consist with any such hostile enterprises against the repose of other nations. In an advanced state of society, therefore, the licence of emigration is, in some degree, restrained; mankind emigrate individually, but not in large bodies, and in this manner they are quietly absorbed in the new communities into which they enter, and to the laws and manners of which they necessarily conform. But though the civilized communities of the world never violently emigrate into each other's territories, they frequently invade the domain of the savage, by obtruding new settlers on his uncultivated territories. These emigrating in considerable bodies, and being provided with every necessary implement either of cultivation or of war, take possession of the soil, which they cultivate for their support, and, gradually increasing in proportion as their improved modes of cultivation draw an increased produce from the soil, all the efforts of the original proprietors to dislodge them are found unavailing. From such small beginnings it is that, in modern times, all the flourishing communities of the new world have had their origin.

Among the barbarous nations of hunters and shepherds, emigration necessarily assumes the character of violence. The earth being already occupied with inhabitants, it is manifest that no large body of emigrants can effect a settlement in any territory, without displacing an equal proportion of the original inhabitants. These, however, will not yield without a struggle; wars naturally commence, which are carried on with an inveteracy suited to the important object at stake; and while the conqueror occupies the vacant ground, the world is thinned of its superfluous inhabitants in these contests for room and food.

The want of subsistence, which thus excites in mankind a restlessness and an impatience of their condition, and finally impels them to emigration, appears, from the experience of all history, to be a most fruitful cause of war; and, in these struggles, the mere savage has little chance against the more formidable violence either of the pastoral tribes, or of civilized communities. By the first he is driven from his ground whenever it can be occupied with advantage for the purposes of pasture; while the civilized inhabitants of the globe occupy his territories with new settlers, who, spreading cultivation over the desert, and establishing towns with all their refinements of arts and manufactures where there was formerly a wilderness, destroy the hunting-grounds of the savage, and expel him with the wild beasts, his natural prey, from these seats of industry. Thus driven farther into the woods, he is reduced to fight for his subsistence with other tribes in the same condition as himself, and with whom he has more chance of waging an equal war. Room and subsistence being indispensable to the farther multiplication of the species, every combined movement among mankind in quest of these objects is the signal of discord; the savage tribes, confined to the more remote and unfrequented parts of the earth, mutually exterminate each other by their constant and ferocious hostility; and the pastoral nations carry on equally destructive contests with each other, or with more civilized communities. Barbarism and civilization are in this manner the natural enemies of each other; and a most inveterate war is the inevitable consequence of this hostility. On the issue of the contest, the very existence of both parties is staked. To the vanquished, nothing remains but to perish by famine or the destroying sword. If the barbarous invaders prevail, all traces of civilization are swept away—the form of society is changed—its institutions destroyed, and the nation itself reduced under the most degrading bondage. If, on the other hand, the barbarians are repelled, they have no refuge from destruction. There is no alternative between victory and death, and thus both parties mutually fight with the fury of desperation. But, where the resources of a civilized state are vigorously called forth for the common safety, those formidable inroads will be generally repelled, and the country saved from the ignominy of a barbarian yoke.

Emigrations by which the Roman Empire was overthrown.

To this principle, namely, the disproportion between the increase of subsistence and of population, we may trace that spirit of emigration and of conquest which prevailed universally among all the pastoral nations of the ancient world. The character and manners of those rude tribes have been powerfully delineated by the eloquent historian of the Roman Empire; and Mr Malthus has added a fine historical sketch of the rise and progress of those emigrations which, after a long train of political convulsions, terminated at length in the subversion of the Roman power. It appears, that all that vast portion of the earth, from the Danube and the shores of the Baltic to the confines of China, was formerly occupied by a population of shepherds. These, though distinguished into separate nations, possessing a strong principle of unity in the common tie of their congenial manners, easily coalesced under an enterprising leader for any scheme of emigration or conquest. Deriving their subsistence from pasture and the chace, their ordinary life was one of constant migration, in which they were inured to fatigue, and instructed in the use of all warlike weapons; they were skilful horsemen—expert in archery and in throwing the lance, and extremely active in all their movements. In this wide ocean of barbarism, the stream of emigration was either impelled eastward, as accidental circumstances directed, against the flourishing empires of Asia, or westward against the Roman empire, within whose precincts the whole civilization of the western world was comprised, and alternately, as it reached either of these empires, their whole collected strength was found necessary to withstand the shock. Of the great empires of Asia some were subverted by the formidable inroads of those wandering tribes; and in Europe, the doubtful balance of the world's destiny frequently trembled between barbarism and civilization. At an early period, Rome was assailed by the inroads of the barbarians, and an irruption of the Gauls had well nigh crushed her rising power. In after times, the Cimbri, emigrating in quest of new settlements, were, after they had destroyed five consular armies, arrested in their victorious career by Marius, when the whole nation almost was exterminated. The subsequent contests of Julius Cæsar, of Drusus, Tiberius, and Germanicus, with the Gauls and Germans, still attested the superiority of the Roman arms, and impressed upon the barbarians a salutary terror of the Roman name. Repelled from the Roman frontier, their superfluous resources would naturally be consumed in intestine wars with each other for room and subsistence, until the power of population renewing the strength of those warlike communities, prepared them for fresh conflicts with the civilized world. Accordingly, we find them, in the decline of the empire, renewing their irruptions on the Roman territory. During the successive administration of a series of feeble princes, the empire was assailed by new swarms, and the degenerate Romans had recourse to the dangerous policy of bribing the enemy whom they could no longer conquer. This fatal disclosure of wealth and weakness soon excited the cupidity of new enemies, who broke through the ill-guarded frontier, and spread terror to the gates of Rome. The country became one universal scene of rapine and oppression, and it was only by the vigour and activity of Aurelian, Probus, and Dioclestian, that the tottering empire was saved from its final overthrow. During this interval, the barbarians wasted their population in bloody hostilities with each other, until nature, more powerful to renovate than war to destroy, recruiting their numbers, enabled them to set out on new emigrations, with undiminished strength. During the reign of Constantine, the whole power of the empire was again called forth to repel a new invasion of those destroying hordes. They were vanquished on every side, and driven into the mountains, where it is calculated that about 100,000 of them perished from cold and famine. Other invaders now arose, who were routed and dispersed with great slaughter by the warlike Julian, and pursued into the gloomy recesses of the German forests; but those signal successes obtained for the declining empire no relief from incessant attacks, and the reign of Valentinian was one continued contest with the invading hosts. "The fate of Rome," Mr Malthus observes, "was at length determined by an irresistible emigration of the Huns, from the east and north, which precipitated on the empire the whole body of the Goths;" and the nations of Germany, goaded on by this powerful impulse, were driven, *en masse*, on the Roman provinces. "An emigration," Mr Malthus continues, "of 400,000 persons issued from the same coast of the Baltic which had poured forth the myriads of Cimbri and Teutones during the vigour of the republic. When this host was destroyed by war and famine, other adventurers succeeded. The Suevi, the Vandals, the Alani, the Burgundians, passed the Rhine never more to retreat. The conquerors who first settled were expelled or exterminated by new invaders. Clouds of barbarians seemed to collect from all parts of the northern hemisphere. Gathering fresh darkness and terror as they rolled on, the congregated bodies at length obscured the sun of Italy, and sunk the western world in night."

So long as such an extensive space of Europe and Asia was occupied by these pastoral tribes, the repose of the civilized world was constantly assailed by their barbarous invasions; and, in the course of their various expeditions, the finest countries of Europe were taken possession of and plundered. The same principle of increase, which was the original cause of all these movements, still continued to operate with undiminished force; but while the central countries of Europe remained in possession of their recent conquerors, there was little chance of easily wresting from them what they had so hardly won; and the spirit of emigration being therefore checked and confined for a time within narrower limits by land, the barbarous nations of the north found vent for their overflowing numbers by sea. During the distractions which ensued in Europe subsequent to the reign of Charlemagne, their maritime enterprises were prosecuted with great vigour, and they spread their devastations over Lower Saxony, Friezland, Holland, Flanders, &c. They ravaged the coasts of France, pillaging and burning her finest towns, and at length obtained possession of some of her finest provinces. The British isles were for 200 years exposed to their ravages; and, during the eighth, ninth, and tenth centuries, their plundering expeditions were directed against all the most powerful nations in Europe, until at length the improving powers of these countries, developed by civilization, and directed by policy, were found sufficient to repel all such irregular inroads. It was in this manner that the growing strength of the European states laid the foundation for that important change of manners among the northern nations, under the influence of which, habits of emigration and plunder have been superseded by the peaceful pursuits of agriculture. From this period, the repose of the civilized world has never been seriously endangered by the migrations of any barbarous nation; and it is not likely that such contests will ever be renewed. The pastoral tribes were formidable from the vast space over which they were allowed to range. They are now reduced within much narrower limits. Most of them have been reclaimed from their rude habits and trained to industry. What has been thus lost to savage life has been gained by civilization. The resources of the one have been increased, as those of the other have diminished. It does not appear, therefore, from the present aspect of the world, that civilized man has any farther injustice to dread from his savage brethren. These views are eloquently enforced by Gibbon, in the philosophical and striking view of the leading causes which conduced to the fall of the western empire, with which he closes his history. "Such formidable emigrations," he observes, "can no longer issue from the North; and the long repose, which has been imputed to the decrease of population, is the happy consequence of the progress of arts and agriculture. Instead of some rude villages, thinly scattered among its woods and morasses, Germany now produces a list of two thousand three hundred walled towns; the Christian kingdoms of Denmark, Sweden, and Poland, have been successively established; and the Hanse merchants, with the Teutonic knights, have extended their colonies along the coast of the Baltic, as far as the Gulf of Finland. From the Gulf of Finland to the eastern ocean, Russia now assumes the form of a powerful and civilized empire. The plough, the loom, and the forge, are introduced on the banks of the Volga, the Oby, and the Lena; and the fiercest of the Tartar hordes have been taught to tremble and obey. The reign of independent barbarism is now contracted to a narrow span; and the remnant of Calmucks or Uzbecks, whose forces may be almost numbered, cannot seriously excite the apprehensions of the great republic of Europe."

Character of the more Modern Emigrations.

In modern times, since the progress of improvement has restrained the licence of those rude tribes, the spirit of emigration and conquest has chiefly appeared among the civilized inhabitants of the world, by whose encroachments the barbarous nations have been oppressed. The discovery of the immense continent of America, which was chiefly overspread with savage tribes, or with nations in the infancy of improvement, presented a vast outlet to the overflowing population of civilized Europe, and the reputed wealth of those newly discovered countries, which were found to contain abundance of the precious metals, soon attracted crowds of adventurers from every quarter. The first expeditions of the Spaniards to the New World were for the undisguised purposes of rapine and conquest. They were purely military, not so much with a view to settlement as to plunder; and it was only after the first race of adventurers had perished, that the emigrants began to establish themselves permanently in the country. With this view they resorted to such measures of violence and cruelty, that, in most cases, they either extirpated the original inhabitants, or brought them under the most galling bondage, and in those parts of the country where they fled into the deserts beyond the reach of their oppressors, and where they subsist in savage independence, the cruel injuries which they originally suffered is still attested in their inveterate hostility to the Spanish settlers. The settlements of the European states in North America were not planned upon exactly the same principles of open violence. The savage tribes, by which this portion of the continent was inhabited, presented no such temptations to the avarice of civilized nations, and the first emigrants who were sent out had nothing else in view but to cultivate the country for their subsistence. Agriculture and not conquest was their original object. They offered no violence to the native tribes. All they required was a space of unoccupied territory on which to settle, which was generally procured without any difficulty. But, as the colony grew and flourished, and began to require an extension of territory, the rude inhabitants of the country quickly perceived that they would soon be dispossessed of their hunting-grounds by the gradual increase of the new settlers. They had committed the capital error of allowing the colonists to take root in the country, and they now endeavoured to correct this error, when it was too late. They accordingly entered into combinations for the purpose of exterminating the invaders of their country, and those infant establishments were alternately assailed by secret treachery or open violence. An equally inveterate warfare was in this manner begun with those who settled for the purposes of agriculture, as with those who had commenced their career with open violence, and the object of contest was the possession of the country. From the rapid multiplication of the new settlers, it was obvious that the land would be speedily overspread with their increasing numbers, and the whole being converted to the purposes of agriculture, there would be no room for the hunting tribes. This was the plain and obvious principle of the war which was now commenced. But the issue of a contest between the civilized inhabitants of the globe, assisted by the modern improvement of fire-arms, and the mere hunter of the desert, could not be for a moment doubtful. The arts and policy of Europe accordingly proved too powerful for the Indian savage. He has been gradually pushed back, by the progress of the European colonies, into his native deserts; and though he has occasionally disturbed their progress by his predatory inroads, yet the inveterate warfare in most cases subsisting between the aborigines and the new settlers, by saving all perplexing or fruitless negotiations respecting the cession of territory, and by reducing the matter to the plain issue of force, has, upon the whole, favoured the progress of the civilized encroacher on the territory of the savage. The war of extermination which was commenced between the two classes was sure to end in the destruction of the native inhabitants. A quicker process, indeed, could scarcely have been devised for clearing the country of its barbarous incumbrances; and, however cruel and unjust this may appear, such are unquestionably the harsh means by which the improvement of the North American continent has been brought about. The poor savage has been driven from his territory and his home to make way for the industrious tiller of the ground. The boundaries of the wilderness have been gradually narrowed by the progress of cultivation,—the country has been cleared of its forests and of its inhabitants by the same merciless process of destruction; and upon the ruins of this state of society the system of social improvement has been reared. To the doubtful frontier of the American territory, where civilized gives place to savage life, it is well known, that crowds of adventurous emigrants resort, dispensing with the advantages, and exempted from all the restraints of social life. Here they act in the double capacity of cultivators and huntsmen, partly civilized, and partly savage, until, by the advance of new emigrants, they are gradually surrounded with improvement on every side, and are at length brought within the pale of order and law. Tired of this control, and anxious to resume their free and licentious habits, they dispose of their lands to emigrants of a more settled character, and again take their station on the verge of the desert, there to bear the brunt of savage hostility, to hunt and to cultivate, and by their resolute and ferocious habits, to repress the inroads of the exasperated Indians, and to act the part of successful pioneers, in clearing the way for the great mass of the American population. It is in this manner that the country gradually assumes the aspect of civilization—that the field are cultivated, and that the dwellings of men are seen to take place of the haunts of wild beasts. It is certain, indeed, that the policy of the American government, in regard to the native tribes, has uniformly been humane and enlightened; their original right of occupancy has always been respected, and the cession of their territory has generally been procured in lieu of some satisfactory equivalent offered and received. But the licentiousness and cruelties under which the Indians have been oppressed, were committed by individuals beyond the precincts of law or government—they were besides glossed over under the specious disguise of legitimate hostility; and there was no one to plead the cause of the oppressed Indians. In these circumstances, the power of government could be exerted with little effect in favour of the native tribes; and accordingly, it is matter of history that many of the finest parts of the American territory were with difficulty wrested from their original possessors, after a most severe and sanguinary struggle.

America, the great outlet to Emigration.

In its present condition, America presents a grand outlet to the surplus population of Europe. It is the natural asylum of all those who are flying in quest of subsistence from the over-crowded communities of the old world. The inhabitants of America have before them an untouched and fertile country, about 2000 miles in extent (counting from their most remote settlements to the Pacific Ocean), in which for centuries to come their population will have full scope to expand. Here there is an ample supply of fertile and unoccupied land, which yields abundance of food, while its cultivation gives rise to a constant demand for new labourers. Wages are consequently high, the labourer lives in comfort; and if he is industrious, he becomes in his turn a purchaser of land, from the savings which he accumulates. If, from the rapid increase of population, the demand for labour should be satisfied, and wages should fall, this is the signal for new emigrations, and for the occupation of an additional portion of the uncultivated territory; and thus the abundance of land, and the constant demand for labour in the western districts, maintains it at a high price in every part of the United States. In these circumstances, it is manifest that a labourer, provided he can transport his labour from the overstocked market of Europe to the understocked market of America, will dispose of it to better advantage. He will unquestionably improve his condition if he can but once reach this advantageous market for his labour. But if he is already sinking under the miseries of his condition in Europe, the expence of a voyage to America, and even if this could be borne, the farther expence of a long journey inland, before he reaches the western provinces, forms, in most cases, an insuperable bar to his emigration; and if the attempt is made with insufficient means, it becomes an extremely hazardous experiment, and may ultimately increase, in place of alleviating, the miseries of the emigrant. That the inland states of America afford extraordinary encouragement to labourers, is a point established beyond all dispute; but the difficulty still remains of reaching this desirable country; and to this, which is the important question, the attention of emigrants should be directed. It is their business to reflect, not merely whether it would be desirable to reach America, but whether they have the means of transporting themselves to so great a distance.

Difficulties and Hazards attending Emigration.

Besides those in the condition of labourers, there is another class of adventurers, to whom emigration to the western states of America presents a favourable chance of improving their condition. These are farmers with a moderate capital. An allotment of land may be purchased in the unsettled parts of the country, at the government price of two dollars *per* acre; and an emigrant who can afford to buy and to cultivate 100 or 200 acres, and acts with due discretion and skill, may not only promise himself a sure asylum from want, but, in the course of a few years, the country being settled all around him, and his property rapidly improving in value, he will realize an independent provision for himself and family. A removal to America, however, like every other important step in human life, should be gone about with caution; it should be undertaken, not upon any romantic fancies of ideal happiness, which are sure to be disappointed, but on sober calculations of prudence. Consequences must be coolly considered—opposite inconveniences deliberately balanced—sanguine expectations must be tried by the test of experience—fancy must give place to reality, and what is calmly planned must be vigorously executed. It is only in this manner, when emigration is deliberately chosen, that it promises to be a beneficial measure; and, even in this case, there are many difficulties and discouragements which the emigrant will have to encounter. These consist chiefly in the difficulty of effecting a settlement, and of subsisting until the land yields its first produce—in the herculean labour of clearing ground which is covered with a thick forest—in the danger to a European constitution from the laborious drudgery of felling trees, and afterwards pursuing game in the woods for a scanty subsistence, during which the exhausted body is exposed to the cold dews of night—and finally, in the unhealthiness of the country in the vicinity of the navigable rivers, where the choicest land is chiefly to be found. All these disadvantages and dangers should enter into the estimate of the emigrant, that, when they occur, they may be resolutely met. From the concurring accounts of all those who have lately visited the United States, it appears that no other class, excepting country labourers, mechanics, and farmers, could be at all certain of improving their condition by emigration. There may occasionally be a favourable opening for the employment of capital in manufactures or in commerce; but opportunities of this sort cannot be reasonably calculated on by those who are at a distance; and emigration with any such views would be a rash and highly ineligible experiment. In the American community, there are no vacancies for professional men of any description.

Emigrations from the Highlands of Scotland.

It has been already stated, that the great cause of emigration is the want of subsistence, and that where a community is prosperous and happy, mankind will follow their natural propensity to settlement and rest. But this general cause is frequently aided by other causes, originating in those changes of manners, to which the progress of society is constantly giving rise. In consequence of that great revolution which took place in modern manners, when the feudal system was superseded in Europe by the progress of commerce and industry, the numerous retainers of the great landed proprietors were thrown loose upon society, and reduced to quit their former abodes in quest of a new settlement. Prior to the improvement of industry, there was no way in which the proprietors of the soil could consume their surplus produce, but in maintaining a retinue of idle dependants, who repaid, by their fidelity in war, the bounty on which they subsisted during peace. No equivalent existed for which they would exchange their revenues, which were accordingly wasted in the most profuse hospitality, and in these times a train of idle retainers was the never-failing appendage of wealth and greatness. But when commerce and industry began to supply the landed proprietors with a new equivalent in which their surplus produce could be expended, their idle retainers were gradually dismissed, and the surplus produce of the soil, by which they were supported, was now laid out by the landlord in expensive luxuries and refinements. In the more improved parts of the country, all those changes have already taken place. The land is invariably let for the highest rent that can be procured, and the superfluous population from which it has been freed is absorbed in the general mass of society. But, in the Highlands of Scotland, these changes are not yet fully accomplished. Traces are still to be discerned of that ancient state of manners which was formerly prevalent all over the country, but which are now fast disappearing before the progress of improved cultivation. Until about the year 1745, the landed estates in the Highlands of Scotland were occupied by tenants, who paid for the possession of the land rather in military services than in money; and though, after this period, these services were of little use to the proprietors, yet from habit, and the influence of old attachments, the tenantry were still continued on their lands. The obvious interest of the proprietor in letting his lands to the best advantage, has gradually broke the force of these old feudal connections, and the hereditary occupants of the Highland estates are now ejected by the landlord, to make way for a more improved mode of cultivation, and for more profitable tenants. Under the old system, as many inhabitants were settled on the land as it could maintain; under the new system, no more hands are maintained on it than can be profitably employed; and the superfluous labourers or tenants, who are thus removed from the spot which their families have possessed for centuries, naturally turn their views to America, where there are boundless tracks of unoccupied land ready to receive them. Their early habits and mode of life entirely disqualify them for mercantile business. Ejected from their hereditary possessions, they are in a manner outcasts in their native land, and, in search of some new place of rest, they voluntarily quit their kindred and their home. Lord Selkirk, in his able publication *On the State of the Highlands of Scotland*, points out the strong motives which prompt the Scotch Highlander to emigration, in preference to settling at home as a day labourer or a manufacturer. "The manners of a town," he observes, "the practice of sedentary labour under the roof of a manufactory, present to the Highlander a most irksome contrast to his former life. The independence and irregularity to which he is accustomed, approach to that of the savage; his activity is occasionally called forth to the utmost stretch, in conducting his boat through boisterous waves, or in traversing the wildest mountains amidst the storms of winter. But these efforts are succeeded by intervals of indolence equally extreme. He is accustomed to occasional exertions of agricultural labour, but without any habits of regular and steady industry; and he has not the least experience of sedentary employments, for which, most frequently, the prejudices of his infancy have taught him to entertain a contempt."

The emigrations from the Highlands of Scotland have always kept pace with the progress of improvement, and, from about the year 1773, they have been continued with little intermission. Of all those who were thus compelled to quit their native land, America became the natural asylum; and to different points of this extensive continent they were attracted by circumstances in a great measure accidental. The first emigrations were undertaken under all the disadvantages and anxiety of imperfect information. But these having succeeded, a more secure foundation was laid for future enterprises of the same nature; and the Highlanders, who were disposed to emigrate, naturally chose the spot where their friends were already settled. In this way, they are scattered throughout different parts of the American continent. Some have formed settlements in the state of New York, on the Delaware, the Mohawk, and the Connecticut, while others have gone to Georgia and to North Carolina, or to the more northerly climate of Canada and Nova Scotia. Their choice of a settlement appears to have been dictated by the natural wish of being near their friends, by whose experience and advice they would be assisted through all the difficulties of a first establishment. A mode of conduct more rational, more calculated for social comfort and for ultimate success, can scarcely be imagined; and if the interest of the emigrant had been alone considered, no other plan would ever have been adopted.

Observations on Lord Selkirk's Plan.

In the emigrations planned by Lord Selkirk, other views were, however, mingled with the original and simple purpose of these expeditions. In place of assisting the Highlanders in their own natural and rational plan of joining their friends already settled on the other side of the Atlantic, his purpose, as he himself states, was to detach them from those natural ties; to counteract the motives which induced them to follow their friends and relations; and to collect them into a new settlement, under the dominion of the mother country. After pointing out the strong inducements which the emigrants have to collect in particular spots, to which the presence of their friends and connections impart the attraction almost of another home, he observes, that, to overcome these motives, it is indispensable that "some strong inducement should be held out to the first party, who will settle in the situation offered to them. To detached individuals," he continues, "it would be difficult to offer advantages sufficient to counterbalance the pleasure of being settled among friends, as well as the assistance they might expect from relations. But a considerable body of people, connected by the ties of blood and friendship, may have less aversion to try a new situation." Lord Selkirk objects to emigration, where the adventurers are allowed to follow their own notions, and settle in detached bodies in different parts of the American territory, because it scatters the national resources, which he proposes to keep together, by inducing the emigrants to settle in the British colonies, "where" he observes, "they would be of national utility," and where all the peculiarities of their language and manners might be preserved. He seems also to imagine, that, if the Highlanders were settled on the Canadian frontier, they would form an admirable outpost to guard the colony from the intrusion of American settlers, and from the worse plague of American principles, of which he entertains a great dread, and against which he considers the inveterate loyalty of the Highlanders as an admirable barrier. In pursuance of those views, a colony of Highlanders was induced, by Lord Selkirk, to settle in Prince Edward's Island, in the Gulf of St. Lawrence, where an establishment was formed, and where, in the course of about two years, a supply of subsistence was produced equal to the wants of the settlers. Another colony was afterwards conducted to the western parts of Upper Canada. Of the progress of this colony, different and contradictory accounts have been circulated. Thus far, we believe, however, is certain, that Lord Selkirk's projects gave rise from the first to a deep-rooted jealousy on the part of the *North-west Canadian Fur Company*; and that, after various acts of hostility and sanguinary outrage, the settlement was attacked by a body of their servants, who barbarously put to the sword the greater part of the settlers, and nearly extirpated the colony. From this calamity it is said to have revived, and, from the accession of new settlers, its inhabitants are reported to amount to about 500.

To the plans of emigration, set on foot by Lord Selkirk, there is this strong and general objection, that they propose to accomplish objects, in which the emigrant has not the most remote interest, and for which all the comfort, as well as the solid advantages which he would derive from the intercourse of his relations and friends, are uselessly sacrificed. The sole purpose for which he quits his country, is to procure a settlement in another on the most easy and advantageous terms; this is his only motive for embarking in so hazardous an enterprise; and whatever is unconnected with his ultimate prosperity and happiness, is entirely foreign to the main object of his voyage. To settle among friends and relations, whose comfort and assistance is material to the emigrant, or in a country which has the benefit of a free and enlightened government, where he is sure of protection, and where, as much as possible, he may have all the helps of civilization to facilitate his progress, is wise and rational; and there is something unnatural, as well as revolting, in the notion of extinguishing all those social feelings, which bind the emigrant to his friends and relations, and which revive, even on a foreign shore, the image of his native land. According to Lord Selkirk's plan, the emigrant is deprived of all these consolations; and he is tempted to try a new situation, for the vague and chimerical purpose of concentrating, for the benefit of the mother country, resources which would be otherwise scattered; or for the still more chimerical purpose of guarding the Canadian frontier from the inroad of American principles. These are political objects in which the emigrant has not the most remote interest. Formerly, the emigrants from the Highlands had almost the whole continent of North America open to their choice. They could settle among their countrymen and relations, amid the blessings of civilization and of regular government. According to Lord Selkirk's plan, they are thrown upon precisely the very worst portion of the American continent—withdrawn from the more genial climes of the South—exposed to the long rigours of a Canadian winter, and separated from their friends. The first body of emigrants, who accompanied Lord Selkirk, were settled on an island in the Gulf of St. Lawrence, in a desolate spot, thirty miles from any habitation, in "circumstances scarcely more favourable," as he himself observes, "than if the island had been completely desert." His second colony was established on the continent, far to the westward of any settlement, and wholly without the precincts of civilization or regular government. It was accordingly either altogether, or nearly crushed by violence; and this fatal catastrophe is a suitable commentary on the original impolicy of choosing the desert for a settlement, and of relinquishing the protection of government, with all the other advantages of a more improved state of society. The happiness and comfort of the colonists, which is the fundamental principle of all colonization, was made subservient, in those plans, to other objects, in the highest degree absurd and chimerical; other interests were allowed to mingle with that great and radical interest; and useless hazards were incurred,—hazards which were avoided so long as the emigrants were allowed to follow the sure and unerring instincts of their own individual prudence.

Controversies and Laws respecting Emigration.

The emigrations to America, which were formerly confined to the Highlands of Scotland, or to some parts of Ireland, have of late years become general throughout the kingdom. The cause has been, as usual, a want of subsistence, originating in the want of employment for the labouring classes. The wars and devastations which had prevailed in Europe for about twenty-five years prior to the last peace,—the unprecedented acrimony of the hostilities waged by the different belligerents against each other's trade,—the interruption, in consequence of their commercial intercourse, and a complication of other causes of mischief, into which it is foreign to our present purpose to inquire, though they were long borne up against by the enterprise and industry of individuals, appear to have at length terminated in a complete and general relaxation of all the great springs of the mercantile community. In these circumstances, numbers emigrated to America with various success, artisans and labourers, as well as substantial farmers. Among others Mr Birkbeck, an English farmer, having sold his effects, embarked with his family for America, and purchased a large track of uncultivated territory on the Wabash, a branch of the Ohio. Having formed an establishment in this remote and sequestered spot, he published, for the benefit of such as were disposed for similar enterprises, an account of his journey and subsequent proceedings, in which he sets forth, in glowing colours, all the advantages of emigration. Other publications followed of an opposite tendency, and a controversy was in this manner begun on this important question. That certain classes of persons will improve their condition by a removal to America, cannot be doubted. But it is equally certain, that the emigrant must lay his account with many difficulties and discouragements, and these, perhaps, Mr Birkbeck has rather thrown into the shade. It must be recollected that he is himself a successful emigrant; perfectly satisfied both with the step he has taken, and with the country; and this disposition of mind, communicating itself to his descriptions, is apt to excite fanciful anticipations, which the event may not realize.

It is singular, that the emigration of inhabitants from one country to another, should, in most cases, be regarded by those who are left behind with the most decided marks of disapprobation. To such length has this spirit been carried, that laws have been passed, obstructing emigration, as if it was an evil; and, with a view of still farther discouraging all such schemes, the most exaggerated accounts have been studiously circulated of the distresses and difficulties in which the poor emigrant involves himself by rashly removing to a foreign land. In the Highlands of Scotland emigration has always been viewed by the landed proprietors with the most extreme jealousy and aversion, although it plainly has its origin in the measures adopted by themselves for the improvement of their own estates. The first step to an improved mode of cultivation is to clear the land of all its useless inhabitants; and the discarded tenants are compelled to seek in a distant land that subsistence which they can no longer find at home. Emigration is the sad alternative which they embrace from necessity; they quit the cherished spot on which their family has been settled for ages, because they can no longer remain, and to refuse them this resource appears both cruel and unreasonable. Under the influence of those prejudices, a law was passed in 1803, for the ostensible purpose of securing to the emigrant good treatment during his voyage, but really with a view, it should seem, of obstructing it altogether. By this law, the most extravagant allowances are prescribed to him both as to room and food, and these he is not at liberty to dispense with. Its effect is consequently to enhance the expence of the voyage, and to obstruct emigration, or, when this consequence does not follow, to waste the stock of the emigrant, by involving him in useless expences, and to land him on a foreign shore with diminished resources. It tends, in this manner, like all the other laws which, in the management of private concerns, officiously substitute loose and inapplicable rules for the prompt sagacity of individual prudence, to injure those whom it is intended to serve. By other laws, emigration, to certain classes, is actually prohibited under severe penalties. An artificer who attempts to emigrate "with the intention of devoting his knowledge for the benefit of foreign countries," is liable to punishment, as well as any agent by whom he is encouraged to such an attempt; and, upon this very absurd law, two convictions actually took place at the Old Bailey in 1809; the one of a master who had offered an artificer advantageous terms to emigrate to the United States, and the other of the artificer who, having no work at home, had accepted of those terms. It deserves to be remarked, that the judge who tried the case, forsaking his own proper province of merely administering the law, commended highly its policy, and dwelt at great length on the mischievous crime with which the prisoners stood charged, as deservedly and severely punishable by law. It is justly observed by Dr Smith, that the industry of an artificer is his only inheritance, and that to prevent him from disposing of it to the best advantage is an unwarrantable act of power. The object of such regulations is to depress the art and industry of other nations, in order to monopolize for our own industry the market of the world. But this project, which originates in mercantile rivalry of the most pitiful description, is as unjust as it is impolitic. We may indeed prevent, by particular laws, the exportation and importation of certain sorts of produce. But no laws can bind up the inventive powers of man, nor can any partial enactments of particular countries retard the improvement of the world. If the general increase of wealth requires a supply of the finer manufactures, and the proper reward is offered, the art and industry necessary to produce them will be called forth, in spite of the regulations which any one state may pass to the contrary. The law, besides, admits of the following simple evasion: The artificer who intends to emigrate, takes his passage as a labourer, and, in this character, he is suffered to depart without farther question.

Although the emigrations which have of late years taken place were manifestly occasioned by the total want of employment and subsistence, owing to the lamentable derangement of commerce, an outcry was, nevertheless, raised against the emigrants by those whom their happier destiny had enabled to remain at home. This is the more extraordinary, seeing that the country is crowded with labourers who cannot find employment, and that it is obvious, that, if there is too little either of subsistence or of employment, the emigration of those who require both to be employed and to be fed, will leave a greater supply for those who remain behind. Wherever there is a greater number of labourers than can be employed, —where wages are consequently low, and general distress prevails, emigration is precisely the most effectual remedy for the evil. In proportion as superfluous labourers are withdrawn from the over-crowded communities of Europe, those who are left behind will enter into more full employment and better pay, and will live comfortably, in place of starving as before. Whatever may become of the poor emigrants themselves, the country from which they emigrate must be benefited by the quantity of labour thus withdrawn from the market. In place, therefore, of seeking to arrest the progress of emigration, it would be wiser to encourage it, and rather to give facilities to those who wish to convey their labour from Europe, where the market is overstocked, to those countries where there is more demand for it. We are happy to add, that, in pursuance of those maxims, a plan has lately (June 1819) been adopted by the British government for encouraging emigration to the Cape of Good Hope, and that a grant of L.50,000 has been voted by Parliament, to be laid out in carrying it into effect. A small deposit of money is required from the emigrant before leaving this country, which is returned to him on arriving at the Cape, with all his other expences. (o.)

ENGLAND.

The *History* of this country, from the earliest accounts to the union of the crowns, is given in the *Encyclopædia*, under the article England. It is continued from that period to the rupture of the treaty of Amiens, under the word Britain; and will be brought down, in this Supplement to the late general pacification and settlement of Europe, under the head of Great Britain. The present article will, therefore, be limited to those inquiries which belong to the *Statistics* of England; but, even in this view, we must leave out such parts of the subject as have been already treated in the *Encyclopædia*, and confine ourselves to the supplying of omissions, and of recent or corrected information.

I.—*Situation, Extent, Face of the Country, Soil, and Climate.*

Situation and Extent.

England, the southern, and by far the most fertile division of Britain, is parallel in latitude with Holland and the North of Germany, extending from 50° to 55° 45′ N. Its figure is nearly triangular, and its extent of coast is very great, both from being much indented, and from the sea bounding it on all sides, except along a width of seventy miles on the Scottish border. The adjacent seas are the German Ocean on the east, St. George's Channel on the west, and the English Channel on the south. No country can be more fortunately situated; its climate is temperate; its extent is sufficient for its political security; while its insular position not only presents the greatest capabilities of aggrandizement in a commercial sense, but has, by rendering a great military force unnecessary, in all probability been the chief cause of preventing the executive branch from usurping absolute power, as in the countries of the Continent.

Its superficial extent had long been a question of considerable doubt, and the different estimates varied no less than ten millions of acres. Mr Pitt, Situation and Extent.

on the authority of Arthur Young, assumed, in 1798, the superficial extent of England and Wales to be nearly 47,000,000 of acres: a later calculation by Dr Beeke, approaching more to accuracy than any preceding one, fixes it at 38,500,000 acres (*Observations on the Produce of the Income-Tax, &c.* 1800); but a still more recent survey (*Report to Parliament on the Roads in* 1818) declares the area of England and Wales to be only 57,960 statute miles, containing 37,094,400 acres.

Face of the Country.

England is, in general, a level country: in the north, Westmoreland, and a considerable part of Cumberland, Lancashire, and Yorkshire, are mountainous, but most of the other counties of England present a succession rather of picturesque eminences than of great elevations; forming a striking contrast to the barren ridges of the northern part of the island, and still more to the abrupt and awful scenery of Switzerland, or the south of Germany. The highest mountains of England are in the north-west, where there are several exceeding 3000 feet in height; of these the most noted, if not the highest, is Skiddaw. Between Lancashire and Yorkshire, there is a range of nearly equal altitude; in Shropshire there are various hills; also in Somerset, Devon, and Cornwall, none of which, however, reach the height of 2000 feet. There is a long hilly range which traverses the southern counties, in a line nearly due east and west from Dorsetshire to Kent; and another that goes in a north-east course from Wiltshire to the East Riding of York, but both are of inconsiderable elevation. The traveller, who proceeds northward from London to York, meets very few hills and hardly one mountain in a distance of 200 miles. To the east of this road, the country, particularly Cambridgeshire, Lincolnshire, and part of the East Riding of Yorkshire, is almost entirely level, and bears a great resemblance to Holland; consisting of fens apparently gained in a very remote age from the sea. In Wales, the face of the country is altogether different, being mountainous throughout, and some of the hills, in particular Snowdon and Cader Idris, attaining a height nearly 3600 feet above the level of the sea.

Sea Coast.

The sea coast of England presents a very different aspect in different situations: in some quarters, as in Cornwall, in Kent, in part of Norfolk, and in Wales, it is steep and elevated; in other parts it is low, sandy, or marshy; exhibiting, on the whole, a variety which hardly admits of being brought under a uniform description; and which, though partaking much more of a level than rugged character, still differs greatly from the opposite shore of Flanders, Holland, and Friesland, which is one continued flat for more than 300 miles.

Rivers.

Of the rivers of England, the largest are the Thames, the Severn, and the Trent. The Thames has no pretensions to romantic effect in any part of its course, nor is its body of fresh water large; but it is navigable for more than 120 miles, and in the approach to London from the Nore, presents to the admiring spectator a prospect, which, whether we consider the quantity of shipping, the thickening population, or the high state of improvement of its banks, is wholly without parallel. The Severn, though not equal to the Tay in quantity of fresh water, is superior to the Thames, and during the first part of its course preserves the characteristics of a mountain stream, being clear, and at times bordered by picturesque scenery; but on leaving Wales, and entering a more level country, it assumes a different aspect, and becomes a full slow-flowing river, admitting of easy navigation, and facilitating greatly the commerce of Shropshire, Worcestershire, and Gloucestershire. Towards its mouth it receives the Wye, a large navigable river from Wales. The Trent rises in Staffordshire, and after a course, often tortuous, but generally in a north-east direction, falls into the Humber, which soon after becomes a broad estuary. The Mersey, as a river, is of no great importance, but as an arm of the sea it affords, from the west, a very capacious inlet to the trade of Liverpool, and facilitates the conveyance of the produce of the interior. The Tyne is a large stream, having Newcastle on its banks, and Shields near its mouth. The Medway, as a fresh water river, is small and sluggish, but acquires, by the influx of the tide, such a width of channel and such a depth of water at Chatham, as to adapt it to the reception of the largest men of war. Speaking generally, it is only the rivers of Wales, Westmoreland, Cumberland, and a few mountainous districts, that are rapid or transparent; the great majority of English rivers, particularly in the eastern and central part of the kingdom, are slow in their course, and owe the degree of beauty they possess, less to the effect of the water or scenery, than to the high cultivation and elegant disposition of the adjacent grounds.

Lakes and Forests.

A similar remark applies to the lakes of England: nothing can exceed the beauty of Winandermere, Keswick, and Ulleswater, while the unvaried and uninteresting collections of water, such as Whittleseameer, and others in the fen district, are to be compared only to those in North Holland or Friesland. In regard to wood, England is very well provided, without having many of those extensive forests which are met with on the Continent on great mountain ranges; such as on the Jura ridge between France and Switzerland, and the Suabian Alps on the Upper Rhine. It is in private plantations of limited extent, but of very frequent occurrence, and sometimes of great beauty, that the chief stock of English timber is to be found. Several extensive tracks, such as the New forest in Hampshire, the Forest of Dean in Gloucestershire, and Sherwood in Nottinghamshire, belong to the Crown.

Soil and Produce.

The soil of England is suited to a great variety of products; but it has not the exuberant fertility of southern climates; much labour and vigilance being requisite to obtain from it a grateful return. The quantity of moisture makes it admirably adapted to pasture; a characteristic which does not particularly strike those whose travels have never extended beyond their own country; but is of the highest importance in the view of those who have visited the Continent, and have witnessed the parched and arid state of the richest plains in the months of autumn. In regard to husbandry, it happens, by a singular coincidence, that, in England as in Scotland, the best is practised in the east part of the island; particularly in Norfolk and Northumberland. As to mineral treasures, the eastern half of England, at least of England to the south of Yorkshire, is remarkable for containing no mines either of coal or of metal; these valuable deposits are to be sought in the more uneven districts of the north and west, viz. in Durham, Westmoreland, Lancashire, Shropshire, Worcestershire, Devon, and Cornwall. In the east, particularly in Lincoln and Cambridgeshire, vast improvements have been made in the present age by draining, but there is still the means of making farther and valuable acquisitions. Much also remains to be done in bringing into culture extensive heaths and moorlands in almost every county in the kingdom; the soil of these is in general poor, but the tillage required would seldom be obstructed, as in many parts of Scotland, by the ruggedness of the surface. Comparing the soil of England with that of the adjacent countries, we find it greatly superior to that of Scotland, except along our eastern coast; it is perhaps better also than that of Ireland, fertile as the latter naturally is; nor needs it, on the whole, dread a comparison with the soil of France, where, amidst districts of great beauty and luxuriance, the eye of the traveller is often struck with extensive tracks of heath or marsh.

The soil of Norfolk is particularly adapted to barley; and the fens of Lincolnshire and the adjacent counties for oats. Leicestershire has long been accounted the first of our grazing counties; Herefordshire takes a lead in orchards; while Surrey and Worcestershire, but above all Kent, are celebrated for hops.

The following table given by Mr Comber, in his treatise on *National Subsistence*, exhibits the results of a computation of the extent of land under cultivation in England and Wales:

	Acres.
Wheat	3,300,000
Barley and rye . . .	1,000,000
Oats and beans . . .	3,000,000
Clover, rye, grass, &c. .	1,200,000
Roots and cabbage cultivated by the plough . . .	1,200,000
Fallow	2,300,000
Hop-grounds . . .	34,000
Nursery-grounds . . .	9,000
Fruit and kitchen gardens .	41,000
Pleasure-grounds . . .	16,000
Land depastured by cattle	17,000,000
Hedgerows, copses, and woods	1,600,000
Ways, water, &c. . . .	1,300,000
Commons and waste lands	5,094,000
Total	37,094,000

The quantity of corn raised *per* acre is, of course very various, according to the soil; 2½ quarters for wheat, four for barley, and 4½ for oats, may be stated as a fair average return; though any calculation from such data must be very vague, as on some spots the produce of wheat amounts to six quarters, in others to only 1½ quarter *per* acre. The average weight of a bushel of good English wheat is about 58 lbs.; in bad seasons, it does not exceed 56 or 57, but in good years, and in the best wheat districts, it is found to weigh from 60 to 62, and in some particular spots 64 lbs. It yields 43 lbs. flour for standard wheaten bread, or 46½ lbs. for household. The culture of rye in England is now much restricted, compared to what it was in former times; also that of buck-wheat, which, under the name of *Sarrazin*, is so common on the opposite coast of France. The cause of this decrease lies in the preference given by our peasantry to wheaten bread, and in the cultivation of more valuable grain on the land formerly appropriated to the inferior sorts. Of hops, the quantity raised throughout the kingdom is necessarily very fluctuating, but it may be computed at an annual average of twenty millions of lbs.

Climate.

The climate of England is that of an insular country of limited extent, subject, in consequence, to rain, and exempt from intensity of either heat or cold. Compared with the adjacent countries, it is less humid than Ireland, which, like Portugal, in a different latitude, is the first land to intercept the vapours of the Atlantic; on the other hand, the climate of England is less dry than the opposite shores of Holland and Germany, to which every wind but the west arrives across a track of continent. The climate of the south of England resembles much that of the opposite coast of Brittany, Normandy, and Flanders; while that of the north is very similar to the temperature of Denmark, which, like the north of England, is a narrow country enclosed on either side by the sea. In regard to the relative degrees of heat or cold, if England has not so much summer warmth as continental countries on the same parallel, she generally escapes in winter that intensity of frost, which in less than 48 hours of easterly wind so frequently seals up their harbours. On the other hand, our weather is much more variable than in the inland part of the continent, and our sky less clear; still it by no means follows that the balance of disadvantage is on our side. The moderate heat and frequent returns of rain preserve throughout the year that verdant pasture which, in autumn, the continent enjoys only in its maritime districts; while those droughts in spring, which are so noxious in the south of France and similar latitudes of the continent, are hardly known among us. In point of salubrity also, we may fairly stand a comparison with our neighbours, for, variable as is our atmosphere, perhaps no country exhibits a larger proportion of examples of longevity.

There exists, however, a considerable difference in the climate of different parts of England. The west, exposed to the Atlantic, and containing hills and mountains which intercept the clouds, is much more rainy than the east, where the aspect of the country is level, and the expanse of adjacent water much less considerable. Another, and equally remarkable difference, arises from latitude, the season being a fortnight or three weeks later in the north than in the south of England. Notwithstanding all the skill of the Northumbrian farmers, the traveller who leaves the harvest finished in the south of England in the first week of September, and who sees the corn cut, if not carried, in the midland counties, will generally find it, in the middle of that month, untouched and standing in most parts of the country to the northward of York. In winter this difference in the temperature of the North and South of England is less perceptible. As to the spring months, March is, proverbially, raw and cold, from the prevalence of easterly winds, particularly in the part of the kingdom adjacent to the German Ocean: April is, in general, wet and favourable to vegetation; but May, though a pleasant month, can hardly be said with us to bring more "indulgent skies." It is in June, July, and August, that our climate takes a more settled aspect; while, at the same time, the power of taking exercise on almost any day is indicative of a very gratifying advantage over the sultry atmosphere of our southern neighbours on the Continent. November, though frequently wet and foggy, is only a prelude to winter; even December does not often bring intense frost, which is commonly reserved to January; and during the last twenty years we have been repeatedly without any frost of consequence, or heavy falls of snow, until a considerable time after the days have lengthened.

Variations of Temperature.

During the six winter months, from October to March, the mean temperature of the central part of England is commonly between 42° and 43° of Fahrenheit. In December, January, and February, it is generally below 40°: In July and August, 62° to 65°. The variations of temperature within the space of 24 hours are felt most strongly in the equinoctial months, March and September. In these there is often a difference of 18° or 20° between the day and night, while, in the summer months, this difference seldom exceeds 12° or 15°, and in December or January, is only from 6° to 8°. The mean annual temperature, noon and night, of the central part of England, is about 50°. The greatest summer heat seldom exceeds 80°, and the cold of December or January is rarely below 20° or 25°. In mild situations in Devonshire and Cornwall, the winter temperature is 2°, 3°, 4°, and even 5° higher than in London. Penzance is the spot in England least visited by severe cold; and it is consequently much recommended in pulmonic cases.

Of rain, the largest proportion falls in the N.W. of England, particularly in Westmoreland and Lancashire, owing to the neighbourhood of the sea and the height of the mountains. There, the average quantity is found to be 45, 50, and, in some situations, 60 inches, while the average of the kingdom at large is from 30 to 40.

Temperature of recent Seasons.

No period has been marked with a more sensible variation of seasons than the last five or six years: the winter of 1813-14 was long and severe; the summer of 1816 cold and wet; the summer of 1818 uncommonly dry and warm. This will at once appear from the state of the thermometer. During the summer of 1815, which may be termed one of medium warmth, the thermometer was at or above 70° during 27 days; in 1816 it rose to 70° in five days only: in 1817, which was also deficient in warmth, it reached or exceeded that limit on 17 days only; but, in 1818, it was at or above 70 during no less than 70 days, and in the three days of greatest heat it was between 83 and 87. In all these instances the case was the same throughout the Continent of Europe; the crop of 1816, for some time very promising, became, in a great degree, lost for want of warmth; that of 1818 proved on the Continent as in England, abundant in wheat and scanty in most other grain; while last winter was equally mild, and the summer of this year (1819) was still more forward on the Continent than in Britain.

Prevailing Winds.

The prevalent winds in England are west and south-west. Our outward-bound merchantmen are often detained from the want of a Northerly or Easterly wind, but it rarely happens that our honeward-bound are kept beating in the Channel by the want of a westerly breeze. In these respects, also, the case is the same on the opposite shores of the Continent; the Dutch and French outward-bound vessels often experiencing detention from the continuance of westerly winds.

II.—*Divisions, Civil and Ecclesiastical.*

The civil divisions of England are those of counties, hundreds, and parishes. The county divisions, like several of our national improvements, take date from the reign of Alfred, and though subsequently increased by the acquisition of the three northern counties from the Scots, have not, in other respects, experienced much alteration since his time.

Civil Divisions.

The 12 counties of Wales, added to the 40 counties of England, make a total of 52. The name of "County corporate" is given to most of the cities of England, and to some of the towns; this distinction, little attended to by the public, and seldom mentioned but in law-papers, implies that the district in question is governed by its own sheriffs and other magistrates, to the exclusion of the officers of the county at large.

The division into hundreds must have originated in a reference to the existing population, and have implied a district containing either a hundred able bodied men, or a hundred families. As population increased very differently in different situations, great inequality ensued in regard to these divisions, and, in the reign of Henry VIII., many of the larger hundreds were partitioned into smaller districts. Hundreds were farther subdivided in the time of Alfred into tithings, or associations of ten men, for the purpose of mutual defence. But both these subdivisions were unknown in our northern counties, from their not having been subject to the Saxon legislator: these counties, on their subsequent annexation to the crown of England, were divided into "wards" and "wapentakes;" terms sufficiently expressive of the warlike character of the age, and of the exposed situation of a frontier province.

Ecclesiastical Divisions.

The ecclesiastical division of England is into two archbishoprics and twenty-four bishoprics. The archbishopric, or "province" of York, though by much the smaller of the two, comprises Northumberland, Durham, Westmoreland, Cumberland, Cheshire, Lancashire, the chief part of Yorkshire, and the Isle of Man: Canterbury extends over all the rest of the kingdom, including even Jersey and Guernsey. The bishoprics are very different in extent of jurisdiction as well as in annual emolument. The *Encyclopædia* contains a list of the dioceses, and of their respective revenues, as entered in the king's books;

but their present incomes are greatly increased, in consequence of the rise in the value of land. The third and most familiar of the ecclesiastical divisions of England is into parishes. This mode of division seems to have existed from a very remote period, and to have continued during the last five centuries on the same footing, with very slight variation, as at present. The total number of parishes in England and Wales is 10,674.

III.—*Harbours, Roads, Canals, Bridges.*

Harbours. We have already noticed the great navigable rivers of England. In regard to sea-ports, after London, which is perhaps the most capacious and happily situated in Europe, the principal are Liverpool, Hull, and Bristol. Liverpool and Hull are situate on great inlets of the sea, while Bristol stands on a comparatively small river, and, though long a seat of commerce, is indebted for its present magnitude to recent improvements.

Liverpool gave the first example of wet-docks, originally on a small, afterwards on an extensive, scale. Hull followed the example, her first dock dating from 1774, her second from 1803. Meantime the metropolis opened successively the West India, London, and East India docks; and in 1805, Bristol commenced a great work of the same description. Considerable extensions of the wet-docks of Liverpool and Hull are going on at present (1819).

The chief sea-ports of England, after the four just mentioned, are Shields (for Newcastle), Sunderland, Whitby, Scarborough, Grymsby, Lynn, Yarmouth, Harwich, Sheerness, Chatham and Ramsgate, on the east coast; Portsmouth, Southampton, Poole, Weymouth, Dartmouth, Plymouth, and Falmouth, on the south; with Swansea, Milfordhaven, Chester, Lancaster, and Whitehaven on the west. In the English Channel, the depth and capaciousness of a number of harbours on our side form a striking contrast to the French side, where there are only St. Maloes, Cherburg, and Havre de Grace, none of which are convenient stations. Our great naval stations, such as Portsmouth, Plymouth, and Chatham, have been already described under DOCK-YARDS.

Roads. It was not until after 1660 that the public took an active part in regard to the highways. Turnpikes were at that time placed on the great North road, in the counties of Hertford, Huntingdon, and Cambridge; but it was not till after the peace of 1748 that adequate exertions were made to redeem our public roads from their wretched state. After 1760, the increasing price of agricultural produce, and the general spirit of improvement, were of the most beneficial operation in this respect; and in the fourteen years from that time to 1774, no less than 452 acts were passed for the amelioration of our roads. It was then also that our inland navigation assumed an aspect of activity. The Bridgewater and Trent canals were begun; yet the number of Canal acts that passed between 1760 and 1774 was only nineteen. The American war interfered considerably with public improvement; and it is only from the date of its cessation that we enter on an active and prosperous era.

Acts of Parliament passed for Public Improvements.

Years.	For Roads and Bridges.	Canals and Harbours.	Inclosing, Draining, and Dividing Land.	Paving and other Local Improvements.	Total for each Year.
1785	31	7	22	20	80
1786	40	4	25	14	83
1787	30	3	19	14	66

1815	44	10	82	26	162
1816	34	4	49	22	109
In 7 years	341	64	738	115	1298

The last period presents a good deal of fluctuation; still the annual average is fully equal to that of the preceding series.

The total length of paved streets and paved roads in England and Wales is (from a Parliamentary return in 1818) nearly 20,000 miles. The total length of all other roads nearly 96,000 miles. In France the highways are under the care of government, and are kept in repair out of the general taxes, without any tolls or turnpike dues; in England they are managed by the respective counties, represented by Commissioners, and no part of the expence comes out of the public treasury. It is defrayed partly by local imposts, partly by dues levied: the local impost is discharged either by labour or by composition money; thus:

The value of labour in kind (on an average of the years ending October 1812, 1813, and 1814) was,	L.535,423
The average amount of composition money, ...	278,506
The average amount of dues or rents levied, ...	601,954
Annual average of the expenditure on the roads of England and Wales,	L.1,415,883

being at the rate of nearly L.12, 6s. 8d. *per* mile. In the Highlands of Scotland, where the travelling is so much less, one-third of this allowance is sufficient for the annual repair of the roads.

Canals. The Canals of England are extremely numerous; no country except Holland entering into competition with us in this respect. Among the principal are the Grand Junction, advancing from London above 100 miles into the midland counties; the Grand Trunk, extending from the Severn northward into Staffordshire, a distance of 139 miles; the Liverpool and Leeds, extending 130 miles; the Oxford 91 miles. To proceed with the enumeration would be almost endless; suffice it to observe, that the English canals are of moderate size, being from 25 to 30, 35, and 40 feet in width, and, in general, from 5 to 6 in depth; the barges navigating them are very long, frequently 70 or 80 feet on a width of 10, 12, or 14 feet; but in many cases their dimensions, at least their width, are necessarily smaller, the less frequented canals being narrower than those we have mentioned. Could the application of steam to navigation have been foreseen, the canals of England would have been made much wider; at present there would be great hazard of injury to the embankments, from vessels so propelled.

Bridges. The principal bridges in the kingdom are the five erected across the Thames at London, three of which have been opened since 1817. Of these, two, the Southwark and Vauxhall, are of cast iron; the former of three very large arches, the latter of nine arches, each of 78 feet span. The first example of an iron bridge on a large scale, either in England or any other country, was that erected in 1796, at Waremouth in Durham, the span of which was 240 feet. In the same year was finished at Buildwas, near Colebrook, Deal, over the Severn, an iron bridge 130 feet in span. See **Bridge** in this *Supplement.*

IV.—*Agriculture.*

Of the state of English agriculture in former ages, we can form some idea from a reference to the acts of the Legislature. In these we find, at a very early date, the traces of that policy which expects abundance and cheapness to result from discouraging the export of corn. No permission of export seems to have been granted till 1394, and then only, on the payment of certain duties: in 1436, some additional latitude was given, and export was allowed, when the quarter of wheat did not exceed a price corresponding to nearly 13s. of our present money. The reign of Elizabeth was the epoch of a great rise in the prices of corn, originating, not as was vulgarly asserted, in the "decay of tillage," but in the sudden depreciation of money, produced (as we have explained under the head of **Corn Laws**) partly by degradation of the coin, and partly by the influx of silver from the mines of America. The complaints of the "decay of tillage," if they express any thing more than the ordinary discontent of the ignorant part of the consumers, are to be accounted for by the gradual consolidation of small farms, and by inclosing land for pasture, with a view to the export of wool. In these days, however, government participated in the prejudices of the people; and the general purport of the acts passed under Elizabeth and her successors, was to shackle export and prevent a rise of price. It was not till the reign of Charles II. (1670) that the export of corn was exempted from a tax; and it is from 1689 that we are to date that fundamental change in our Corn Laws, which encouraged export by a bounty.

The prices of corn in England have been regularly noted only since the middle of the seventeenth century; yet this comparatively short record is of importance, as indicating very remarkable fluctuations. The price of wheat, which, in the beginning of last century, was 50s. became reduced to 40s. 30s. and eventually, in the ten years between 1740 and 1750, to so low a rate as 24s. a quarter. No wonder that the culture of corn should now receive a check, and that a large proportion of our arable land should be transferred from tillage to grazing. The effect of this conversion, and of an increasing population, raised the price of corn in the ten years from 1750 to 1760, to an average of 42s. 6d.; and, in a few years more, turned the scale from export to import; a change which, with more or less fluctuation, has continued ever since. From 1764 to 1790, the average price of wheat varied from 42s. to 50s.; our annual imports from 200,000 to 500,000 quarters of all kinds of corn. But since 1792, the average prices have been from 50 to 60, 70, 80, 90, and even 98s.:* our annual imports from half a million to two millions of quarters of corn of all kinds.

These periodical statements are useful in showing the proportion that our corn produce has at different times borne to our population. Another mode of forming an idea of the progress of agriculture is by the number of acts of Parliament passed annually for inclosing common-land. The first parliamentary act that seems to have been thought necessary, or of which we have a record, was in the reign of Charles II.; the next in that of Queen Anne. From this time forward, such legislative permissions were accounted indispensable preliminaries to inclosing commons. We subjoin a list of them from the proceedings of Parliament.

---

* See the Article **Corn Laws**, Vol. III. p. 352, of this *Supplement.*

	Inclosure Acts.	Average Number of these Acts annually.
From 1719 to 1759, there were passed . .	249	8
From 1764 (when the price of corn rose) to 1779,	941	58
The absorption of capital in the American war affected the extension of tillage, and the average, from 1780 to 1794, was only	445	30
The high prices of 1795 and 1796 multiplied inclosures, and produced for those two years, .	146	73
From 1797 to 1803, both years inclusive, .	581	83
From 1804 to 1811, ditto,	736	92

Since 1811, the change in political circumstances has caused considerable fluctuation. We add the number of acts in each specific year.

In 1811 (high prices), . .	134
(This is the greatest number in any year.)	
1812 (very high prices), . .	123
1813 (peace had become probable),	117
1814 (peace), . . .	119
1815 (prices had fallen greatly), .	82
1816 (great agricultural distress), .	49

The average extent of each inclosure is computed at 1200 acres; the outlay about L.10 *per* acre.

The total superficial extent inclosed, in virtue of acts of Parliament during the last 100 years, may be calculated, or rather guessed, at nearly five millions of acres. These acts relate only to England and Wales; for in Scotland such improvements do not require a special authority.

Size of Farms.

We have already, in the article AGRICULTURE, treated of the points of superiority in our husbandry over that of the Continent, ascribing it to various causes, and to none more than the medium size of our farms, which differ equally from the large unmanageable tracks held by Polish noblemen, and the diminutive occupancies so common among the French peasantry, particularly since the Revolution.

The size of farms in England is greatest in the best cultivated districts; that is, in the counties to the east of the metropolis,* viz. Kent, Essex, Suffolk, and Norfolk. Farms are extensive, also, in Northumberland. In these counties, the engagements of farmers are for larger sums than in East Lothian, Berwickshire, or any part of Scotland; rents being frequently from L.800 to L.1200 and L.1500 a-year. In more retired districts, particularly in Cumberland, Westmoreland, and Wales, the occupancies, whether farmed or held in property, are in general very small; and an average of all the farms of England and Wales would not much exceed L.150 a-year.

Leases in England are, with the exception of particular districts, granted for seven years only; when the term is longer, the case is peculiar, and applies to land that evidently requires very extensive improvement. Farms are also let occasionally from year to year. There is in such cases something like an assurance, on the part of the landlord, that the tenant shall not be removed for a certain number of years, or that otherwise the improvements shall be considered and allowed for. When a tenant holds from year to year, there is a written agreement, with specified covenants; the tenant being subjected to fines in the event of a deviation from them.† Both methods are highly injudicious; and it is in the prevalence of them, more than in the existence of tithes and poor's rates, that we are to look for the backward state of agriculture in many of our finest counties. No class of men have more liberality than the English landholders; but it would be in vain to expect a tenant to lay out much capital on the improvement of a farm of which his tenure comes to an end in seven years, or may be disturbed by the commission of a trespass, or the occurrence of a death. A tenant so situated loses the habit of reflecting on improvements, and even of carrying into effect those which he is aware would, in time, be advantageous. If he succeed in saving money, he is much more likely to place it out at interest than to employ it in his own business.

Expence of Cultivation.

The expence of cultivation has increased greatly during the present age; the enhancement consequent on war and taxation not having been counteracted in agriculture, as in manufactures, by ingenious discovery, improved machinery, or any great augmentation of capital. The following table contains the averages of three distinct years, at periods considerably remote from each other.

Average Expence of Cultivating One Hundred Acres of Land, for three distinct years. ‡

	1790.			1803.			1813.

* Arthur Young *On the Progressive Value of Money*, p. 7.

† Evidence of Surveyors in *Corn Committee Reports*, 1814.

‡ Returns made to the Board of Agriculture, and published by Arthur Young.

The last column may be taken as a fair representation of agricultural expence at the present time. There have been reductions in some particulars, especially labour and taxes; the tax on horses employed in husbandry (17s. 6d. a-head during the war) having been materially reduced in 1816; but this is balanced by some additional expences, particularly the charge for manure, which is not fully stated in the above column. Surveyors are accustomed to calculate the produce of land with reference to the rent: highly cultivated land ought to produce three rents, that is, one-third of the gross produce should go for the rent, another for the expences, and the remainder for the farmer's profit; inferior land, requiring additional expence in cultivating, the rent is in general only a fourth, sometimes only a fifth, of the gross produce.* It was in 1813, after the discomfiture of Bonaparte in Russia, that land surveyors began to lower their estimates of rent, in the prospect of peace.†

Cattle, Sheep, &c.

A century ago, our cattle, from feeding on wastes and commons, were not one-half, sometimes even not one-third of their present weight. To calculate the number of cattle in England is a matter of considerable difficulty. It is commonly computed to contain from 4,000,000 to 5,000,000 oxen. Horses are, of course, much less numerous, and do not appear to exceed 1,500,000, of which about 1,000,000 are used in husbandry, 200,000 are kept for pleasure, and 300,000 are colts and breeding mares. In all these departments of rural economy, an increase of number takes place as improvements are introduced, and pasturage ameliorated; but, in one of the humbler objects of a farmer's care, we mean poultry, the progress of society operates to produce a reduction. This is owing chiefly to the number of farm houses diminishing as farms increase in extent, and to the abridged supply of that waste provision which forms the chief food of poultry.

The number of sheep in England is a point of interest, both in a manufacturing and agricultural sense. We are inclined to take the average at 18,000,000 or 19,000,000 sheep, and 7,000,000 lambs. The number of long-woolled sheep is fully 4,000,000; their fleeces average 7 or 8 lbs.; of short-woolled sheep the quantity is much greater, and probably exceeds 14,000,000; but the average weight of fleece is only from 3 to 3¼ lbs. The whole quantity of wool annually shorn in England seems above 80,000,000 lbs. The merinos were introduced about the beginning of the present century, and were imported in large numbers after our alliance with Spain, in 1809. Opinions differ in regard to their utility, the carcase not having answered so well as the fleece. Considerable advantage, however, has been derived from crossing them with our own breeds, and farther experience may lead to more beneficial results.

The great pasturage counties are Leicester, Northampton, Lincoln, and Somerset. Of the counties for butter and cheese, the principal are Cheshire, Gloucestershire, and Wiltshire. Of butter, England, from the richness of her pasture, should naturally make large exports; but taxes press so much on our agricultural produce, that our Custom-house returns exhibit no shipments worth notice, except to the Brazils and to our own colonies in the West Indies and North America. In fact, in this respect, our agriculturists have stood in need of prohibitory duties on the produce of the Continent.

Import of Butter and Cheese into Britain from the Continent, chiefly from Holland. ‡

	Butter.	Cheese.
In 1812, . .	25,867 cwt.	87,657 cwt.
1814, . .	115,776	145,562
During nine months of 1815, . .	90,000	76,630

At that time the rate of duty on foreign butter imported was only 5s. 1¾d. *per* cwt.; on foreign cheese only 4s. 4¼d. *per* cwt.; but, in 1816, these duties were quadrupled, and the imports greatly reduced. From Ireland, the imports of butter to London only were, in 1812, 160,000 cwt.; in 1816, they were of nearly equal amount. At that time prices were low, but, since the imposition of the high duties on Continental butter, the Irish are assured of a steady demand and good price for this very important article of their produce.

A national peculiarity, of some importance in itself, and claiming our notice in connection with the nature of our climate, is the much larger consumption of butcher-meat among the lower orders of our people than in the same class on the Continent, particularly in France. This has long been the case. It was a saying of Prince Maurice of Nassau, the able successor of the first Prince of Orange, that the English soldiers newly come over were, on account of their generous food, "fit for enterprises of high mettle." §

Rate of Farming Profit.

The annual amount of profit from farming, that is, the return for the capital and personal labour of farmers throughout the kingdom, is as little susceptible of a definite calculation as any thing in the range of statistics. It can be judged of only by approximation, and by adopting the broad rule of land surveyors, who, in their estimates, assign an equal sum for farming profit as for rent; this gives nearly thirty millions for the farming profit of England and Wales; an estimate confirmed by the returns under the property-tax, as well as by the probable amount of the farming capital of England, viz. between L.250,000,000 and L.300,000,000 Sterling.

Total Annual Produce of England.

Connected with these calculations, is the value of the *total* annual produce of land in England. This is necessarily subject to fluctuation; the high price of a particular season leading, in the next, to an extended tillage, and *vice versa*. Taking wheat at the medium of 80s. and other corn at the prices at which importation begins to be allowed, we shall find an average produce of somewhat more than sixty millions Sterling in corn; to which, adding a similar value in pasturage, and a farther allowance for hops, fruit, and vegetables, we have a total of from 130 to 140 millions. Such seems to be the collective value of the annual produce of the land of England and Wales, and of the labour and capital bestowed on it. That this estimate is not materially wrong, appears from a reference to the government returns of rent (under the property-tax), which, in 1810, amounted to nearly thirty millions; and it is common to consider the rent from a fourth to a fifth of the gross produce.*

* Evidence in *Corn Committee Reports*, in 1814.

† Ibid.

‡ Returns to the House of Commons, 1816.

§ Sir William Temple *On the Netherlands*, Chap. IV. p. 102.

Comparison with Scotland and the Continent.

In Scotland the rent bears a higher proportion to the gross produce; being in general not less than one-third. (*Evidence in Corn Committee Report*, 1814.) This is owing, certainly, not to greater capital, and still less to superior soil, but to an exemption from tithe and poor's rate; also to the use of long leases. A farther difference of rent in favour of Scotland is found, on examination, to be but apparent, and is explained by the larger size of the Scotch acre. It is in tillage, not in pasturage, that the Scotch farmers lay claim to superiority. On comparing English agriculture with that of the Continent, we find that our chief superiority consists in machinery and live stock. Thrashing machines are, in a manner, unknown on the Continent, and all iron manufacture is of inferior quality. In regard to live stock, the countries that approach nearest to us are Jutland, Holstein, Holland, Flanders, and Normandy, all evidently indebted for their extensive pasturages to the vicinity of the sea; in the interior of the Continent, pasturage is, in general, very indifferent. Even in these maritime provinces, the cattle, though frequently large, are not fattened in the same gradual manner as in our grazing counties; the meat, consequently, is not of equal flavour. In horses the inferiority is more apparent to the eye, and holds both as to size and shape. Flemish horses are large, but heavy, while the Norman breed, though capable of much labour, is small in size when compared with the English. No where are horses seen of such bulk and strength as the drays in London: if they are, as is supposed, of foreign origin, they have greatly surpassed the primitive stock, since neither the Netherlands nor Holstein can now match them.

The Corn Committees of Parliament, in 1813 and 1814, collected a great deal of useful information relative to the agriculture of the Continent, and the price at which foreign corn could be imported into England. That price is not so low as may at first be imagined. In Poland, land and labour are very cheap, but the means of bringing down the grain from the interior are very limited. The great rivers are navigable only at particular seasons, and the labour of conveyance is considerable, when we take into account the bringing back the barks with men and oars against the current. It is thus profitable to ship for England only when the London market is at or above 70s.† The quantity of wheat annually exported from Poland varies from 200,000 to 500,000 quarters; that from Pomerania, and the rest of Germany bordering the Baltic, from 100,000 to 150,000. Flanders seldom makes a large export; the year 1810 affording almost the only example of the kind in the present age. In Russia, the price of wheat, though considerably lower than in England, is said to have risen since 1780 in nearly the same ratio; and in France, landed property is burdened with a direct tax (the *foncier*) of 25 *per cent.* on the rent, which, of course, enhances materially the price of produce. These facts are useful in enabling us to arrive at a definite conclusion on a topic hitherto involved in vagueness and obscurity,—the relative prices of corn in England and the Continent. To consumers on the spot, prices are, on an average, about 30 *per cent.* below our peace currency, which corresponds to a difference of 25 *per cent.* when the freight and other import charges are added to the price on the spot. In butcher-meat, the Continent, in general, is also about 30 *per cent.* below the peace prices in England. The variation of prices among the continental countries is much smaller than we generally imagine; and the variation from season to season is also much less than in England, because butcher-meat enters comparatively but little into the food of the lower classes.

We cannot close this part of our subject without a few remarks on the connection between the state of our agriculture and the extent of our financial burdens. Those who compare the heavy pressure of our taxes with the lighter burdens of our continental neighbours, have, in general, the satisfaction of finding some counterpoise in the superior dexterity of our people, and the productiveness of our capital. This holds true, in regard to our navigators, our merchants, and our manufacturers; and it holds in agriculture in regard to grazing; because in grazing little personal labour is requisite, while capital and active habits of business are of the most beneficial operation. But, in the department of tillage, much remains to be done ere England can claim any great superiority. Farms are yet too small in more than two-thirds of England; and leases generally too short. The course of husbandry is frequently injudicious, the ploughs on a bad construction, and there exists a gross misapplication of animal strength. However light the soil, and however strong the horses, it is still customary to put three, four, and frequently five, in a plough, throughout almost all our west and south-west counties. These are the main causes of the comparative unproductiveness of our finest counties, and of our being obliged to pay so heavy a premium in the shape of corn laws to support our agriculture. Without the corn laws, our lower classes would be supported on nearly the same terms as their continental neighbours;

---

* See the preceding Table of the number of acres under cultivation in England; also the article Corn Laws, p. 364.

† Evidence of Mr Jolly, *Corn Committee*, 1814.

Mines, Quarries, &c.

and there would be no occasion, with all our taxes, to dread the competition of foreigners in almost any branch of industry; but, if the manufacturers of England are obliged to pay for their support 30 *per cent.* more than those of France and Germany, while their wages are very little higher, what other prospect have we than that of increasing emigration, and the augmentation of the poor rates?

The quantity of land still lying uncultivated in the shape of wastes and commons, is a frequent topic of animadversion; persons unacquainted with agricultural calculation calling loudly for their being brought into culture, while the landed interest object to passing a general inclosure act, or, in other words, to giving unlimited scope to speculative cultivation. We by no means participate in their apprehensions; but we would abstain from giving any artificial stimulus to this, more than to any other branch of industry. Let the progress of inclosure be regulated by the gradual increase of our population, and the discovery of better methods of turning such land to account. No benefit can be derived from applying to this purpose any more capital than goes into it voluntarily; and every experienced farmer is aware, that the best prospect of profit lies not in reclaiming new soils, but in bestowing farther labour and expence on the land already under culture.

V.—*Mines—Quarries—Iron, Copper, Tin, and Salt Works.*

In regard to minerals, England does not yield to any country in Europe in natural abundance, and takes the lead of all in the extent to which these rude treasures have been converted to purposes of utility. Our great superiority lies in our coal-mines, which are not only more productive, but much more advantageously situated than those of the Continent. To the mines along the coast, a ready conveyance is afforded by our insular position, and to those in the interior by our inland navigation. The consumption of coal in England, for domestic use, has been computed, or rather guessed, at 15,000,000 of tons annually. Large as this quantity is, and larger as it must be, when we add to it the vast consumption of manufactories, such as iron-works, salt-works, glass-houses, &c. there is no reason to apprehend the exhaustion of this precious mineral; the depth of the coal beds being very great, and the extent of ground containing them amounting to many hundred thousand acres. The principal tracks for coal lie in Northumberland, Durham, Derbyshire, Staffordshire, and Glamorganshire. The ports for shipping it in large quantities are Newcastle, Sunderland, Swansea, and Whitehaven. The motive of the tax on coal exported to foreign countries is thus neither an apprehension of eventual scarcity, nor even a calculation of revenue, so much as a dread of giving our continental neighbours the means of rivalling our manufactures. Coal is not wanting in France and Germany, but the mines are at a distance from water-carriage, and as yet very imperfectly wrought, while for domestic fuel the inhabitants give a preference to wood.

——— to other parts,	12,000
	665,000[*]

All these statements are taken from *Returns to the House of Commons in May and June* 1818.

To Scotland, a considerable quantity of English coal (about 40,000 chaldrons) is shipped annually. In Wales, the coals carried coastways are chiefly from Swansea to Beaumaris, and vary from 20,000 to 30,000 chaldrons: the culm carried coastways in Wales goes chiefly to Pembroke, Cardigan, and Beaumaris, and is computed about 18,000 chaldrons.

Of inland coal, the consumption in London is very inconsiderable, the duty not exceeding L. 1600 a-year. Recent discoveries in regard to the application of steam, both for cooking and for warming apartments, appear to promise a considerable reduction in the consumption of coal. Much apprehension was excited in the coal counties, by a proposition brought forward in the present year (1819), for an equilization of the duty on coal, on the plan of relieving London and the maritime counties, by finding an equivalent to government in a reduced tax imposed on all coal, or, to use the technical phrase, on "coal at the pit's mouth." This equivalent might have been found by a very reduced rate of tax, since the whole of the coal that at present pays duty appears to be below a fourth, perhaps below a fifth, of the total consumption. But this apparently small tax was represented as replete with ruin to many of our manufactures, whose situation had been determined by the cheapness of coal, and whose preservation depended on a continuance of this advantage. The petitions soon became so numerous and urgent, that Ministers hastened to announce that the idea was wholly relinquished on their part, and the question, when brought forward by an individual member, was lost by a great majority.

Quarries.

In quarries, whether of stone or slate, England is not rich, particularly the eastern half of the kingdom: hence the almost universal use of brick in ordinary buildings. It is not till the traveller reaches Durham, that he finds stone commonly used. In the northern counties, quarries occur frequently; in the south those of Portland and Bath are the most considerable. Still the annual profits of the whole are inconsiderable, when contrasted with the product of our mines, as appears from the following return:

Profits in 1810 *from the Quarries, Mines, and Iron Works in the counties where they are principally situated; extracted from the Parliamentary Papers on the Property-Tax.*

Iron Mines and Works.

No branch of our industry has increased more rapidly in the present age than our iron-works. A century ago, it was computed that we required an annual import of 20,000 tons of foreign iron; an import that for many years seems to have been on the increase, so as to carry the quantity required, after the middle of last century, to 30,000, 40,000, and even to 50,000 tons. This supply was brought to us from Sweden and Russia, and though burdened with duty, it was, in quantity, more than double our native produce. Fortunately, after the year 1780, discoveries were made which increased greatly our supply at home. Bar iron had been manufactured in England, as on the Continent, with charcoal fuel only, coal being deemed inapplicable to that purpose. Under that impression, the rapid consumption of the wood in the neighbourhood of our different iron-works, had necessitated a removal, at a great expence, of materials from one spot to another, and was on the point of causing an alarming decay in the business, when our iron-masters, after long perseverance, succeeded in applying coal to their manufacture. They had to contend with various prejudices, particularly the supposed inferiority of iron so made; but, in the course of years, the manufacture acquired such an extent that there were, in 1805, 220 established blast-furnaces, making 250,000 tons of pig-iron. No sooner had the trade acquired this extension, than government fixed on it as a fit object of taxation, and proposed a duty on iron of 2s. *per* ton; a proposition which experienced the most decided resistance from the body of iron-masters. They urged that, to put iron-works under the regulation of the excise, would interfere materially with the manufacture; that there would be great difficulty in apportioning the drawback on the hardware articles exported; and that the expected produce of the tax would be most decidedly lessened by the additional cost of the cannon, muskets, nails, and iron-work of various kinds furnished to government. Besides, a tax on iron must be charged on articles of the greatest utility; on the implements of agriculture, manufactures, and mines; on the iron materials used in our buildings and machinery as a substitute for timber; on our rail-roads and other undertakings of great national importance. These arguments prevailed; the Ministry of 1806 desisted, and no subsequent attempt has been made to impose a duty on iron. (*Papers printed by the Iron-masters, in* 1806.)

The principal iron mines are in Derbyshire and Glamorganshire; but there are extensive mines in other counties specified in the prefixed table. The return of peace, by suspending entirely the demand of government, caused a long and general inactivity in this important manufacture: many of our iron-works were suspended, and the workmen with their families reduced in 1816 and 1817 to great distress. Temporary relief was afforded them by private subscriptions, and by the application of the poor's rate; but it was not until the revival of business in the latter part of 1818, that the workmen were restored to employment, or enabled to earn even a scanty livelihood. Now that the works throughout the kingdom are in activity, the computation is, that 300,000 tons of pig-iron are produced in the furnaces of England, two-thirds of which are made into malleable iron, the other third into castings. The capital invested in these works is reckoned at L.5,000,000 Sterling; the population employed by them at 200,000; the whole, exclusive of the capital and population employed in the manufacture of hardware, of which we shall treat in the section on MANUFACTURES.

Copper.

Copper-mines have long been known in England, but they were wrought with very little skill or effect until towards the year 1700. Even at that time the annual produce, after smelting the metal from the ore, was only a few hundred tons of copper; and it hardly exceeded 1000 tons annually down to the middle of last century. From that time forward the increase became considerable, as well in Cornwall as in Devon, North Wales, and Derbyshire; in all of which copper mines were discovered and wrought. In North Wales there were two mines (Parys and Mona), which, for some time after the year 1780, yielded annually a large quantity of ore, but they are no longer productive: the mines of Devon and Derbyshire continue to be wrought, but the great product is from Cornwall, the mines of which yield 80,000 tons of ore annually: the metal obtained varying from 5 to 15 in the 100 parts, may be stated at 8000 tons of copper. It is the Welsh collieries that afford to Cornwall, as to Devonshire, the great means of smelting; and as the ore is less heavy than the coal required for this operation (one ton of ore requiring from two to two and a half tons of coal), the practice is to convey the ore in vast quantities to Wales, particularly to Swansea. The total quantity of coal consumed for this purpose at Swansea is nearly 200,000 tons a-year; exclusive of a farther consumption of coal at the copper-mines of Cornwall, in working the ponderous steam-engines used in throwing out the water from the pits. In this, as in other minerals, France is greatly behind England. She has various copper mines, but her coal mines, at least hitherto wrought, are at too great a distance to make such undertakings profitable; she consequently requires an annual import from England. For the destination of our exported copper, we refer to the following table:

British Copper exported in 1817, *wrought and unwrought.*

	Cwt.
From London,	85,029
—— Liverpool,	32,989
—— Bristol,	6,150
—— Swansea,	5,740
—— Other parts,	3,237
	133,145

To the following Countries.

	Cwt.
East Indies,	52,595
United States,	22,733
France,	14,550
West Indies,	11,180
Brazil,	8,382
Holland,	7,798
Other parts,	15,907
	133,145

The price of copper in 1746, and the succeeding years, was generally about 1s. 3d. *per* lb.; in 1765, it fell to 1s. 1d., in 1778 to 10d.; since 1781 it has not been under 11d. In 1805, it reached the unexampled price of 1s. 11d. *per* lb.; and large importations took place during 1806, 1807, 1808, 1809, and 1810; but the average price of the last 60 years may be called 1s. 2d. In using copper for coin, it has been proposed to take 16d. *per* lb. as the rate of value, which would leave a profit to government on the mint operation, without affording a temptation to individuals to melt the pieces. (Grenfell *on Copper Coinage*, 1814.)

Tin.

Cornwall is also the great seat of the tin-mines of England. A century ago the average produce of

our tin-mines hardly exceeded	1500 tons.
From 1720 to 1740, the average produce was	2100
From 1740 to 1760	2570
From 1760 to 1780,	2740
From 1780 to 1800,	3100

The produce of the mines does not materially differ from the last of these averages. From abroad we receive tin from one quarter only, viz. the East Indies, in particular from the Island of Banca. Of this we imported, in 1815 and 1816, nearly 600 tons, the chief part of which was re-exported to the Continent of Europe. Of our own tin, about the half is used at home, and the other half finds its way to the following countries:

Return to Parliament of British Tin Exported:

	In 1815. *Cwt.*	In 1816. *Cwt.*
To Russia,	5,556	6,139
Germany, including Prussia,	670	3,482

France,	1,002	2,809
Spain,	220	1,396
Italy,	1,118	3,412
Malta,	232	1,088
Turkey,	3,708	4,252
East Indies, and Asia generally,	9,447	7,733
All other parts,	2,338	3,263
	24,891	35,136

Lead.

The lead mines of England are principally in Cumberland, Northumberland, and Derbyshire; the whole calculated to produce from 12,000 to 15,000 tons annually. Black lead is found in abundance in Cumberland, in the romantic district of Borrodale; but the mine is opened only periodically, that the market may not be overstocked.

Salt.

Salt is already a very important product in England, and is likely to become much more so from the measures urged of late years on the Legislature, part of which have been adopted, while a farther part seem only to wait a season of less financial pressure. (*Report of Committee on the Salt Duties*, June 1818.) Salt is obtained in several ways; partly from brine springs, partly from the rock, partly from sea water. In the last manner it is manufactured in various salt-pans along the coast, viz. in Hampshire, Kent, and Essex; also in the northern counties of Durham and Northumberland, where the abundance of coal cheapens materially the expence of the process. But the great supply is from the rock salt and brine springs of Cheshire, situated in the southern part of the county, near Northwich. From these springs it is obtained (see the article CHESHIRE) at the rate of one gallon of solid salt from four gallons of liquid, while common sea water does not yield above one in twenty-eight. The price of rock-salt at the rocks is only 12s. *per* ton; it is there mixed with the brine from the saline springs, and refined in large iron pans, after which it is called white salt, and is sold, the inferior at 23s. the best from 35s. to 40s. the ton. On salt for home consumption there has been, since 1805, the enormous duty of 15s. *per* bushel, nearly fifteen times the prime cost. The sale price was thus raised to L.30 the ton. This duty has rendered to government, since 1805, no less than L.1,400,000 nett; it is, besides, of easy collection, from the mines and manufactories of salt being confined to particular districts, and smuggling readily prevented.

This concentration will, it is hoped, be the means of facilitating materially the expected changes in the law, since it will render practicable the use of rock salt duty free to certain manufactures (as sal-ammoniac, magnesia, and Glauber's salt) without any great risk of fraud on the revenue. An act of great importance was lately passed (27th June 1817), permitting the free use of rock salt, not only in curing fish, but in making mineral alkali, an ingredient of great use as a substitute for barilla, in the manufacture of soap. This alkali is subjected to a duty, which, it is believed, may soon be raised to 10s. *per* cwt., producing about L.400,000 to the revenue. Were the whole salt duty taken off, the mines and springs of Cheshire might produce annually 24,000,000 bushels of salt, each bushel of 56 lbs.; but the actual quantity extracted, as appears by evidence before a Committee of the House of Commons, in May 1817, is only about 10,000,000 bushels.

	Year 1813.	1814.	1815.	1816.
	Bushels.	*Bushels.*	*Bushels.*	*Bushels.*
Northwich salt exported (this is duty free),	7,754,000	8,677,000	11,595,000	8,392,000
Northwich salt delivered for the fisheries, also duty free, . . .	984,000	1,106,000	1,087,000	702,000
Northwich salt which paid duty, .	937,000	897,000	933,000	893,000

The capital vested in the works is about L.700,000; and the persons employed, including women and children, about 2400.

Our agriculture has already felt the good effects of the recent relaxation of the salt regulations. The high duty of 1805 had necessitated the absolute loss of a quantity of refuse, thrown out from the salt-pans, and eagerly bought up in former years by farriers. This precious manure is now restored, and affords the means of giving fertility to 100,000 acres annually. On salt used for feeding cattle, this duty is reduced to 5s. a-bushel. For bleaching or refining, salt is delivered duty free; in the latter, the quantity used considerably exceeds 1,000,000 bushels a-year. (*Return to House of Commons,* 2d April 1818.)

VI.—*Fisheries.*

A season of peace is always favourable to the extension of our fisheries; and, if we may judge from the progress lately made, this branch of our national industry is likely to be carried much farther than at any former period of our history. Of this we shall treat more fully under the article FISHERY. At present our space allows no more than a brief notice of the principal branches of our fisheries.

Mackerel. The mackerel fishery is strictly English, and is carried on with great vigour on the coasts of Kent and Sussex, in May, June, and July. Large as the supply is, it would still admit of augmentation; and herrings, also, might be caught in vast quantities on the coast of Kent, in October and November. The *desideratum* with the fishermen, now that peace has reduced their expence, is not so much a high price as a certain market; and the most effectual way to procure that is, to quicken, by every possible means, the conveyance to London. The navigation of the Thames not being at all times certain or expeditious, it was proposed some time ago (in 1812) to improve, or rather to re-make, the road to London from the small harbour called Holyhaven, situated on the Essex side of the river, about 30 miles from the metropolis. The late discoveries in the mode of applying steam to navigation, may perhaps render this unnecessary, but it cannot supersede another and more important plan, that of accelerating, by improvements in the roads, the conveyance of fish by land carriage from Brighton, and other parts of the Sussex coast to London. An association of gentlemen, under the name of the *Downs Society of Fishermen's Friends,* was formed in the end of 1815; they have since made several interesting reports, and give reason to hope that various improvements will be effected.

Pilchards. The pilchard fishery takes place chiefly on the coast of Devonshire and Cornwall, and, though subject to great fluctuations as well from the seasons as from our political situation relatively to the Continent, forms, on the whole, an important branch; employing a number of seamen both in catching the fish and in carrying it to foreign markets. Its season is generally from June to September.

Herring. The herring, the most important of all our fisheries, is happily now in a state of rapid extension. It formed, during the seventeenth century, the great employment of the Dutch seamen, and was contemplated by their neighbours with very jealous eyes. Accordingly, in the reign of Charles II., particularly after the rupture with Holland in 1672, several acts were passed for the encouragement of our fishermen, and in a spirit of hostility to the Dutch. The subsequent accession of William to our throne, and the long friendship between the two countries, relaxed the exertions of government; and it was not till after the peace of 1748, that a large bounty was given on the tonnage of the busses, or masted vessels, so employed. Still our fishermen proved unable to compete with the experience and patient perseverance of the Dutch, and it was found necessary to raise the bounty from 30s. to 50s. *per* ton. This had the desired effect, and the number of busses increased; but the additional 20s. being withdrawn in 1771, the fishery again declined. The American war, and, subsequently, the wars of the French revolution, proved extremely adverse to its extension: at last, in 1808, an act was passed, carrying the bounty to L.3 a ton on the busses, with a farther grant of 2s. *per* barrel on all herrings caught whether in busses or boats. This important act was farther confirmed in 1815, and the bounty *per* barrel raised to 4s., with the essential qualification that the herrings should be gutted before curing. A farther and still more important law (27th June 1817) declares, that not only common salt, but rock salt, which is much cheaper, may be used duty free for our fisheries.

These acts form the grand charter of the British fisheries. The bounty, which was formerly reckoned by the tonnage of the shipping employed, is now awarded on the quantity caught, the barrels being branded by customhouse officers. The mode of curing adopted by the Dutch has been communicated to our fishermen, and bounty refused in all cases in which either the herrings or barrels were in improper condition. The success has been correspondent: successive reports made by the *Commissioners of the Herring Fishery*, in 1816, 1817, 1818, and 1819, concur in exhibiting a progressive increase in the quantity gutted before curing, and, of course, entitled to the higher bounty. The increase of our fishing-craft, however, has been only in the number of boats. In the busses, or masted vessels, there is no augmentation, the bounty, even on its present footing (L.3 *per* ton), being insufficient to counterpoise the superior economy of the boats. (Fraser *on the Fisheries.*)

Whale Fishery. Greenland was first discovered by the English, but in this, as in other branches of navigation, we long allowed the Dutch to take a lead. It was not till after 1750 that, government having granted a bounty of 40s. a ton on every vessel employed in the whale fishery, a considerable increase took place in this branch.

In 1750, the vessels employed were only 19; in 1756, they had increased to 67. The war soon caused a decrease of one-half; but, at the return of peace in 1763, this fishery revived, and in 1770, the vessels employed amounted to 50; in 1773, to 55; in 1775, to 96. The American war again caused a decrease, and in 1782, the vessels so employed were only 38. In 1784, they increased to 89, and in 1785, to 140; after this they exceeded 200 annually till 1793; but the long continuance of the late wars reduced them below the half; and the advantages of peace have been counteracted by causes which have as yet prevented the English vessels from regaining the number employed previous to 1793.

Newfoundland. The Newfoundland fishery has been considerable for fully a century past; as a nursery for seamen, it is accounted of such consequence as to have formed the object of a specific article in most of our treaties of peace. The fish caught, particularly in time of peace, is sent less to Britain than to the Catholic countries in the south of Europe; a market subject to all the interruptions attendant on a change of political relations. The number of vessels employed in this fishery at different times was as follows:

In 1731, ... 70
1764, ... 140
1774, ... 254
The American war caused a diminution, but in 1784 the number was . . 236
1785, ... 292
At this rate the fishery continued until the war of 1793, after which, particularly after our rupture with Spain in 1797, it fell off greatly; the fishing vessels in 1798 being only . . . 140

The continuance of war, and the aggrandizement of the French in Italy, occasioned additional depression, so that, in 1810, the number of our vessels employed at Newfoundland did not exceed 92. The peace seemed to promise a revival of this important nursery of seamen, and, in the year 1816, the number of vessels that arrived in Newfoundland was 795, manned by 6000 seamen (*Report of Committee* in June 1817, p. 7); but the trade, both then and in 1817 and in 1818, proved unprofitable, in consequence of indifferent seasons, of the high duty imposed on fish imported in British vessels into Naples, and of the competition of the French fishermen, who are supported by a high bounty from their government. It will thus require a considerable time to reinstate this branch of our fisheries. A treaty with the United States, concluded in the end of 1818, determines the limits within which the shipping of each nation have the power of fishing.

It is matter of surprise to foreigners that a maritime nation should not have more effectually cultivated this great means of facilitating the support of our population. The ample supply that might have been afforded by the Nymph Bank, on the south-east coast of Ireland, has been avowedly neglected; and it is but very lately (October 1818) that we made the discovery of a Bank of almost equal productiveness in the vicinity of Orkney. Fish is little known to the mass of the people in our inland counties. While the value of the butcher-meat annually consumed in England exceeds L.30,000,000 Sterling, the value of our fish caught on our coasts and rivers hardly exceeds L.2,000,000. Yet its price, with the economy and improved arrangements attendant on a state of peace, would not exceed 20s. a cwt., while other animal food costs fully three times that sum. It might easily be conveyed in a corned state by light waggons through the interior of the country. The *London Association for the Relief of the Poor* made, in 1812, some most encouraging experiments in this respect; having forwarded corned cod, in quantities of one or two tons, to various manufacturing towns. This cod, on being steeped 48 hours in cold water, was found to eat with potatoes almost like fresh fish. And all this was done on an extensive scale at the almost nameless sacrifice of L.55. A spirited imitation of this example would greatly increase our exports of fish to Spain, Portugal, and the Mediterranean; while at home it would afford the readiest means of supplying a nutritious food to the lower orders; a considerable proportion of whom must, from the nature of our poor-laws, perhaps from unavoidable causes, continue for a length of time a burden on the community. To accomplish this effectually, the duty on salt ought to be entirely taken off. Fishermen living in hamlets or in detached cottages along the sea-side, can never conform to the rules of the excise, and will never, without their complete removal, be able to fish at any day and hour that may suit their other avocations. Every great fish-market should have beside it a salting-house for curing the fish remaining unsold at a prescribed hour; these might afterwards be sent into the country, or put apart for a winter store.*

VII.—*Manufactures.*

Woollen Manufactures.

In this great department of our productive industry, we begin with woollens, which, although no longer the largest of our manufactures in point of export, nor even in the value annually made, is entitled to the first place from the priority of its establishment, as well as from the substantial basis on which it rests. England, from the extent of her pastures, abounded in wool from a very remote age, and the inhabitants were, doubtless, capable of manufacturing it into rude clothing; each weaver working in his separate cottage, and with very little aid from machinery. In the twelfth and thirteenth centuries, we appear to have had only the most humble fabrics, and to have imported all cloth of finer texture; sending abroad our wool in quantities to Flanders, a country whose inhabitants were at that period much farther advanced than the rest of Europe, with the exception of Italy. It was in the middle of the fourteenth century that a better system was introduced. Flemish manufacturers were invited over to England, and improved greatly the quality of our home made woollens. The seats of this branch of industry appear at that time to have been Kent and Essex; afterwards Gloucestershire, and subsequently the West Riding of Yorkshire. It occupied at first the southern and most improved districts, and spread afterwards to the northward, on account of the cheapness of labour, the abundance of coal, and the convenience of waterfalls for the machinery. The general character of the woollen manufacture of England has been that of slow progress, but of little fluctuation; the latter evidently a consequence of its depending much more on home consumption than on export. It was extended, not like cotton and hardware, by means of discovery and invention, but by the progressive increase of our population; having been so considerable in the end of the seventeenth century, that the total value of woollens manufactured was computed at eight millions sterling, of which five were for home consumption, and three for export. In the long period from 1700 to 1780, the exports experienced a regular, but not rapid rise; amounting in the latter years (after distinguishing between the real and the customhouse value) to an average of six millions sterling, while our home consumption increased in proportion to our augmenting numbers. After the peace of 1783, woollens partook of the benefit of several of the mechanical discoveries and inventions of the cotton manufacture, and continued to extend, notwithstanding the competition of other countries, as appears by the following table:

Export of Woollen Manufactures, not official, but real value.†

1790, (peace)	L.7,300,000
1791,	7,700,000
1792,	7,700,000
1793, (war)	5,200,000
1794,	6,600,000
1795,	7,600,000
1796,	9,000,000
1797,	7,400,000
1798,	9,700,000
1799,	10,200,000

Of these extensive exports, the largest proportion went to the United States; our shipments thither in 1770 exceeded L.2,000,000, and, increasing regularly with the capital and population of America, amounted, in 1799, to L.4,000,000. Holland was also a good customer; and to Portugal and Spain our exports were not inconsiderable. From 1800 to 1807, the woollen manufacture was, on the whole, thriving, and our exports were large and steady; but after 1808, the Orders in Council, Bonaparte's prohibitory decrees, and our unfortunate disputes with America, caused a great fluctuation and diminution in our exports.

---

* Sir T. Bernard *On the Employment of the Labouring Classes.*

† *Official* value is distinct from *real* value, being a computation founded on a series of rules for estimating merchandise by the package, prescribed so long ago as the year 1696. The increase in the value of commodities since then, though very different in different articles, has been fully 50 *per cent.* on the whole, which it is necessary to add, to arrive at the *real* value.

Export of Woollens from Britain.

1808,	L.7,280,370
1809,	8,124,226
1810,	8,659,821
1811,	6,564,817
1812,	7,627,486

The political agitations of these years were productive of great distress among the woollen manufacturers, particularly in 1811 and 1812, as was but too amply shown by the mass of evidence collected for the repeal of the Orders in Council in the latter year. This distress would have been still greater, had not the large demands of government for army clothing in some degree supplied the blank.

Export of our Woollens in Peace.

Years.	Value.
1814,	L. 7,567,507
1815,	10,198,334
1816,	8,404,481

We select 1815, a year of large export, for the purpose of showing the proportion in which our woollens are sent to different countries.

YEAR 1815.

Countries.	Value. (Real not Official.)
Germany, including Prussia,	L.539,745
Netherlands,	383,446
Portugal,	727,805
Spain,	281,610
Gibraltar,	137,605

West Indies,	357,896
Colonies of other powers,	427,431
To all other parts,	251,873
	L.10,198,334

The year 1799 was one of unexampled demand and high price. An inquiry, instituted the year after by Parliament, into the state of the woollen manufacture, afforded a variety of useful *data* relative to the extent of capital and number of persons employed. The result, as far as the name of result can be given to inferences founded on a partial knowledge of facts, was, that the

Total annual value of woollens manufactured in England was	L.20,000,000
And the value of the raw material,	6,000,000

leaving a much larger proportion for wages than in the case of our cotton manufacture;—a circumstance which would be of very serious import to a country so much more loaded with taxation than its neighbours, were it not in a considerable degree counterbalanced by the raw material being of home growth.

It was computed in 1800, that of the whole woollens made in England, more than a third was manufactured in the West Riding of Yorkshire; a proportion which, from the advantages of this quarter over others, is now, we imagine, not far below one-half. Wiltshire, Gloucestershire, and Somersetshire, are the other seats of this manufacture. For shipping our woollens, London was long the only considerable port. About the year 1700, the usual exports were to the value of a million from the outports, and of two millions from London, where the business was managed by the Blackwell hall factors; but since inland navigation has become extensive, the Yorkshire woollens, even when bought up by London merchants, are in general exported from Liverpool.

Extensive as are our sheep pastures, our manufacturers find it necessary to make an annual importation of foreign wool. This takes place from different parts of Europe.

Countries from which Wool was imported into England in 1815.

	Lbs.
Germany,	3,137,000
France,	757,000
Portugal,	1,146,000
Spain,	6,929,000
Ireland, and Isle of Man,	1,355,000
Other parts,	1,667,000
Making a total of	14,991,000

(*Customhouse Returns to Parliament,* 1816.)

These importations being duty free and operating materially to keep down the price of English wool, the venders of the latter. or, as they are termed, the wool-growers, have of late years been very urgent with Government to impose a duty on foreign wool, not on the Spanish, which they admit to be necessary as a mixture with our own, but on those species of foreign wool which come more immediately into competition with their own growth. They took occasion, under the auspices of Lord Sheffield, to bring their claim before Parliament during the agricultural distress in 1816; but the committee appointed to consider of it made no difficulty in declaring, that no part of that distress arose from an inadequate price of wool; and the evident impolicy of burdening a raw commodity which employs the labour of so many thousand individuals, prevented ministers from listening to such applications, until the financial difficulties of the present year led at last (Mr Vansittart's *Speech,* 7th June 1819) to the proposition of a small duty calculated to produce L.100,000. The importations are a full tenth of the total consumption, having in 1818, as in 1814, exceeded 15,000,000 lbs. The wool-growers complain of the great pressure of taxation, but the price has also risen considerably since the beginning of the wars which aggravated our financial burdens.

In the twelve years that elapsed from 1789 to 1800, there took place a rise of 20 *per cent.*: of the subsequent prices, an idea may be formed from the following table:

Prices of Fleece Wool in the years between 1801 *and* 1815. (*Evidence before the Committee on Seeds of Wool*, in 1816.)

Years.	Best Sussex Downs, *per lb.*	
1801	21*d.* to	22*d.*
1802	20	22
1803	19	21
1804	22	24
1805	28	30
1806	22	24
1807	22	24
1808	23	24
1809	32	36
1810	28	30
1811	20	21
1812	23	24
1813	23	24
1814	26	28
1815	21	24

The quantity of wool grown, on an average, in England is 144,000,000 lbs.* two-thirds of which consist of short clothing wool, and one-third of a much more valuable kind, called long combing wool: the latter has, it seems, never been produced on the Continent of a quality equal to ours, except in some small districts in Flanders. The ordinary length of the staple of foreign wool is about two inches; that of our long combing from five to seven inches. Without the latter, the continental manufacturers cannot equal us in the stuff goods and others made from fine worsted; and hence the importance, say our woollen manufacturers, of keeping the law as it stands; that is, not only of receiving foreign wool, but of preventing the export of our long wool.

The progressive augmentation in the import of Spanish wool is of importance, as indicating the increased fineness of our cloth.

	lbs.
In the early part of last century, this import did not exceed	1,000,000
It increased very slowly, for, on an average of five years, ending with 1776, it was not quite	1,600,000
But in the five years ending 1787, it was nearly	2,000,000
In the five years from 1787 to 1792, it exceeded	3,000,000
From 1792 to 1800, the average was nearly	4,000,000
Since 1800, though fluctuating from political causes, it has considerably increased, and now averages nearly	6,000,000

Cotton Manufacture.

Our cotton manufacture is entitled to the greatest attention on different accounts. Of all our manufactures, it affords the largest export, and exhibits the most rapid improvements in machinery. Its introduction, though not remote, is less recent than is commonly supposed. It appears to have taken place about two centuries ago, when it was established at Manchester; but it was long conducted on a very limited scale. The raw material, imported at first only from the Levant, in particular from Smyrna, began, after 1660, to be supplied by our West India colonies. The quantity imported amounted, about the year 1700, to 3500 bales; but, increasing with the extended cultivation of our colonies, it averaged, about the year 1720, something more than 7000 bales. From the colonial conquests of the war of 1756, our import of cotton received a farther augmentation; but the manufacture increased very slowly, a great part of our cotton being re-exported to Holland, for the supply of Dutch and German weavers. It was not till after the peace of 1763, and the invention, first of a carding machine, and next of the spinning jenny, that this manufacture became considerably extended. In 1775, the average import of cotton approached to 18,000 bales. A variety of improvements, explained in our article on COTTON MANUFACTURE (pp. 396, 397), now took place, and increased the average import of the raw material, in 1781, to 25,000 bales. Fine calicoes and muslins were now introduced; the workmen were withdrawn from their detached dwellings, and collected into large factories; and the price of the finished article experienced a reduction, notwithstanding a rise in the raw material, and the wages of labour. The period that followed the peace of 1783 is perhaps unexampled in the history of human industry, for the rapidity of discovery, the reduction of price, and the extension of sale that took place in regard to cotton goods. The unexpected commencement of hostilities in 1793 gave this branch of our industry a severe shock, but the improvements in machinery continuing, the cotton manufactures soon recovered, and increased beyond expectation; requiring a progressive and large augmentation of the import of the raw material, as appears by the following table:

	Bales or Packages of 275 lbs. each.
Average import of cotton in five years, ending with 1796,	98,000
Average of the next five years, ending with 1801,	153,000
Average of the next five years, ending with 1806,	214,000
Particular Years.	
1807,	283,000
1808, (Orders in Council),	168,000
1809, (Orders in Council relaxed),	440,000
1810, (ditto ditto),	561,000

---

* Maitland *On Wool*, a pamphlet published in 1818.

Manufactures.

Particular Years.		Bales or Packages of 275 lbs. each.
1811,	(Distress of trade; suspended intercourse with the United States),	326,000
1812,	(War with the United States),	261,000
1813,	. . .	249,000
1814,	(Peace), .	288,000
1815,	. . .	369,000
1816,	. . .	369,000
1817,	. . .	479,000

Of these large imports, a very small part came from the Levant, our original source of supply; our West India colonies contributed more; the East Indies sent at times large, at other times insignificant shipments; Brazil was more regular; but the grand supply was from the United States, where, in the southern provinces of Carolina and Georgia, the culture of cotton has been rapidly extended since 1790. Of the cotton now imported into Britain, a very small part, at present not more than a twentieth, is sent out unmanufactured; a large proportion (from an eighth to a tenth) is manufactured in Scotland; the residue is all worked up in England. The total value of the cotton manufacture of Britain (cloth and yarn) is computed at somewhat more than L.30,000,000 Sterling.

The rapid rise in the general price of commodities, in the present age, has induced many to consider enhancement as the unavoidable consequence of extended commerce, and to question the accuracy of Dr Smith's opinion, that the diffusion of productive industry has a tendency to cheapen produce, but never was there a more satisfactory confirmation of the arguments of Dr Smith than in the progress of the cotton manufacture. The price paid for spinning a pound of cotton thread, which, in 1786, amounted to 10s. was reduced progressively to 8s., 6s. 8d., 4s., 3s. and 2s. 6d., not by lessening the gains of the workmen, but by a series of inventions for abridging labour; until the great improvements after 1795 led to a reduction of the spinning price to 8d. *per* lb., at which it has since continued. In like manner, the sale price of cotton yarn has progressively decreased, notwithstanding the rise in the raw material.

Price per lb. of Cotton Yarn. (*No.* 100.)

Years.	Price.	Years.	Price.
1786,	38s.	1805, .	7s. 10d.
1790,	30s.	1806, . .	7s. 2d.
1795,	15s.	1807, . .	6s. 9d.
1800,	9s. 5d.		

The prices have since varied from 6s. 9d. to 4s. 5d. according to the state of the trade; and amidst all these reductions, the quality of the yarn is much improved.

Value of Cotton Manufactures and Cotton Yarn Exported from Britain.

	Manufactures.	Yarn.
1814,	17,394,000	2,907,000
1815,	19,127,000	1,781,000
1816,	13,079,000	2,707,000

We add some farther particulars for one year, to show the countries which take the largest proportion of our cottons.

Export of Cotton Cloth from Britain in 1816.

	Printed Calicoes *Yards.*	Plain Muslin *Yards.*
To Germany, .	16,902,000	5,575,000
the Netherlands, .	7,601,000	3,200,000
Portugal, . .	5,725,000	1,925,000
Italy, . . .	4,454,000	2,790,000
Gibraltar (as a *depot*),	5,168,000	2,157,000
Malta (ditto),	2,406,000	3,210,000
Denmark, . .	571,000	445,000
Ireland, . .	146,000	123,000
India and China, .	969,000	462,000
United States of America, . .	16,922,000	5,495,000
British North America,	1,988,000	344,000
Brazil, . .	7,960,000	2,800,000
West Indies and Spanish America, .	15,792,000	4,760,000

It is of importance to remark the quantity sent to Germany, notwithstanding the rival manufactures in that country. To France, our avowed exports are inconsiderable, there being a duty on the import of British cottons; but large quantities are taken off by French smugglers. The demand from the United States is at present, and is likely to continue, the greatest of all; that from Brazil is deserving of attention, as well from its steadiness as from its magnitude, when we consider that the population in that country, accustomed to wear European manufactures, does not exceed a million of souls. Gibraltar and Malta serve as *entrepôts* for the supply of the south of Spain, and other parts of the Mediterranean.

The following short table is useful, in pointing out the countries which carry on more or less of the cotton manufacture, without making the yarn (at least the whole of the yarn) themselves.

Cotton Yarn Exported to the following Countries.

	1814.	1815.	1816.
Russia, .	L.669,000	.494,000	L.408,000
Germany, .	1,600,000	857,000	1,754,000
Netherlands,	462,000	248,000	281,000
Ireland, . .	116,000	107,000	79,000
France, . .	7,780	78	978
Italy, . . .	21,752	12,495	48,302

The insignificance of the export to France, implies not that the manufacture of cotton in that country is of trifling amount, but that the French import the cotton wool direct from the countries of its growth, and manufacture their own yarn.

Loaded as we are with taxes so much heavier than those of our neighbours, it becomes a question of great interest, and anxiety, whether we are likely to maintain our superiority in this, the greatest branch of our exports? With the view of facilitating this inquiry, we shall hazard a conjectural estimate of the component parts of the cost of our cotton manufactures.

Cost of the raw material, .	L.11,000,000
Wages of men, women, and children, in peace, . . .	8,000,000
Salaries of clerks and others, not comprised under wages, . .	1,000,000
Interest (at 5 *per cent.*) on the supposed capital invested in buildings, machinery, and mercantile credits, .	2,500,000
Annual wear and tear of the machinery and buildings, . . .	2,500,000
Profit of the manufacturers, exporters, and venders, . . .	3,000,000
Duty on raw material (about L.400,000); loss by bad debts, travelling charges, postage, and a variety of expences exclusive of the above, . .	4,000,000
	L.32,000,000

The total number of persons employed, directly and indirectly, in the cotton manufacture of England, is computed at from 400,000 to 500,000. Machinery performs here a vast deal; and manual labour, when requisite, can be done in so many instances by women and children, that the average wages of all persons so employed, is not reckoned more than L.15 *per* head *per annum.* The points in which foreigners have the advantage are fortunately limited to the wages and the duty; the last of which it is not impracticable, in a time of exigency, to take off. In other respects, viz. in the purchase of the raw material, the command of fuel, moderate interest of capital, machinery, and subdivision of employment, we stand either on equal or better ground. The wages form certainly a heavy drawback on our side of the question, but, on the whole, the chances in a continued competition seem to be in our favour, as our readers will see by a reference to our article on Cotton Manufacture. To the remarks there made, we have now to add, that at Paris and its vicinity, which is in part the seat of the French manufacture, the support of a workman and his family (and consequently the wages) is fully as expensive as in Lancashire, while at Rouen the difference against us is not considerable. To Switzerland, a similar argument applies, while Saxony and Austria, the other seats of continental competition, though cheaper than England, are remote from the sea, and consequently subject to a heavy carriage on the raw material.

The seats of the cotton manufacture of England are, *first,* Manchester, which takes decidedly the lead of all other places; afterwards Preston, Bolton, Blackburn, and Wigan, all situated in Lancashire. After these come several other places, partly in Lancashire, in Cumberland, and the West Riding of York. The introduction of cotton works into the last, the great seat of the woollen manufacture, is owing to the practicability of the same workmen turning, in case of need, from wool to cotton, and *vice versa.* The master-manufacturers in the cotton trade are not, as in the woollen, a host of individuals with small means, and great only from their multitude; they consist of a limited number of mercantile establishments, each possessed of considerable capital. But in other respects, the parallel is less favourable to the cotton manufacture. From its dependence on foreign demand, it bears many characteristics of a business of speculation; the workmen being at one time in great request, at another reduced to wages quite inadequate to the maintenance of their families; hence that frequent recurrence of complaint and combination against the masters.

Hardware.

We have already noticed the surprising increase in the produce of our iron mines since 1780. This increase of the raw material, joined in some cases to the command of coal in the vicinity, and in all to a facility of conveyance of coal and iron by canals, has given, in the last forty years, a great extension to our hardware manufacture. In it we take as decidedly the lead of foreigners as in our cottons; and if the ratio of increase has not been altogether so rapid, it is owing, not to inferior ingenuity in the workmen, but to radical differences in the two manufactures. In no department has the subdivision of employment been carried to so great a length; in none are its effects in cheapening production so conspicuous. Birmingham and Sheffield are the two great work-shops for our hardware; the latter is confined to iron and steel; while, in the former, not only iron and steel, but copper and brass, constitute the materials of labour. Sheffield fabricates articles which are less for ornament than utility, and which possess, in general, a certain bulk, such as grates, spades, sickles, files, knives, fenders, fire-irons; while in Birmingham, there is, in addition to articles of solidity, a surprising variety of toys, fancy goods, and petty manufactures; each trifling when considered separately, but the whole forming an aggregate of great value. The most insignificant of these, such as a brass-cock or a button shank, passes through a number of hands; each artisan performing only a single operation. He thus acquires an extraordinary dexterity in his limited department, and, in the course of a day, dispatches several hundred, perhaps a thousand articles, through his particular stage, the result of all which is, that the price, when sold in quantities, is incredibly low. Another and very interesting feature in the situation of Birmingham, is the populousness of its neighbourhood. The manufacturing district, extending about sixteen miles, is estimated to contain 300,000 inhabitants, in addition to nearly 100,000 in the town. (*Committee on Repeal of Orders in Council,* 1812.) Yet in none of our large towns is living less expensive; an advantage owing partly to the abundance of coal, partly to the ready supply of milk and vegetables consequent on the wide space occupied by these extraordinary numbers.

The nail trade is carried on, not in the town of Birmingham, but in a part of the district just described; it is computed to employ 30,000 men, women, and children; for even this heavy article admits of a subdivision of employment, which lightens the labour, and enables a workman to avail himself of the aid of his family. Of the two towns, Sheffield is by much the more ancient; the command of coal and iron in the same neighbourhood having rendered it, so far back as the thirteenth or fourteenth century, a place for the fabrication of the homely articles used in

Manufactures.

these days of our ancestors. It is about a century since its razors, knives, and files began to take a more delicate shape. Birmingham embraced a wider range, and advanced with much greater rapidity; but Sheffield also has its adjacent district inhabited by manufacturers, though to a much less extent than the vicinity of Birmingham. This district, called Hallamshire, extends six or seven miles to the west of Sheffield.

Hardware is made in several other places, such as Wolverhampton, Dudley, and Walsall. Each of these towns is situated in Staffordshire, and, in point of manufacture, is small only in comparison with Birmingham or Sheffield. Articles, apparently very trifling, are made to a surprising extent in different places; such as pins at Gloucester; needles at Redditch in Worcestershire; watch movements and main springs at Prescott in Lancashire. The total value of our articles of iron, steel, brass, and copper, including the manufacture from its earliest to its most finished stage, is necessarily fluctuating, but may be computed at L.15,000,000 annually; two-thirds of which appear to be consumed among ourselves, while the other third is exported to two great markets, the Continent of Europe and the United States. A return during three years of peace, but of unequal mercantile prosperity, will suffice to show the average of annual export.

Metals and Hardware Exported from Britain.

	3,442,332	5,468,318	4,892,924

The number of persons, young and old, employed in our hardware manufactories, is reckoned between 300,000 and 400,000. In no branch of industry is the transition from war to peace more sensibly felt; government, the great customer for arms and artillery, withdraws entirely from the market; while the stagnation of commerce, the postponement of new buildings and new machinery, in short, the various evils inseparable from a sudden and general change, which have been so cruelly felt throughout Britain since the peace, all operate most materially against the sale of the heavier and more useful articles. Similar causes cast a damp over the purchase of ornamental and fancy goods; so that, in no department of our population have the sufferings of the labouring classes or the augmentation of the poor's rate been greater. But there is happily a point beyond which depression cannot go, the reduced price of a commodity rendering it applicable to more extended uses, and adapting it to the means of humbler customers. Iron has not been found suitable as a substitute for stone in paving the streets of the metropolis; but, if its price continue low, it is likely to supplant timber for a variety of purposes, of which the public at large are not as yet aware. Reduction of price will lead also to a demand from the Continent for our hardware; the article in which of all others the French and Germans are most behind us. Their mines of iron are seldom adjacent to their mines of coal, and, with the exception of a few places, such as Liege in the Netherlands, and St Etienne near Lyons, the hardware workmen are not collected in such large associations as to admit of the necessary subdivision of labour. As improvement advances, and a taste for comfort becomes diffused, the inhabitants of the Continent will extend their purchases; they will see in the keys, the locks, and other neat and convenient articles of English fabric, a substitute for the bolts, the latches, and other coarse contrivances, with which they have hitherto been obliged to content themselves. In the United States, iron and coal are found, it is said (Mellish's *Travels in America*, chap. 67), in abundance, in a quarter (Pittsburgh in Pennsylvania) where land and provisions are certainly much cheaper than in Britain; but the scattered state of American population must, during several ages, oppose serious obstacles to the division of employment necessary in all the nicer branches of the hardware manufacture; particularly as the ease with which the Mississippi and Ohio are navigated by steam, opens even the western states to the import of British goods. On the whole, therefore, we look on our hardware manufactures, notwithstanding their present depression, as resting on a solid basis, because in them we combine several advantages;—the raw material, the command of cheap fuel, and the use of machinery, which, the more it is adopted, will bring a greater proportion of the work within the compass of women and boys, and thus lesson the proportion borne in the cost of the finished article by wages.

Linen Manufacture.

Linen has never formed one of the stable manufactures of England, flax having been less cultivated among us than on the opposite shore of the Netherlands; a country which, in the fourteenth and fifteenth centuries, supplied the rest of Europe both with the finest linens and woollens. When England subsequently advanced in manufacturing arts, the abundant supply of wool pointed out the most suitable branch; and we were contented to continue our imports of linen from the Netherlands, from France and from Germany, or to favour the manufacture of the sister island in a department which did not excite our jealousy. In Ireland, the linen manufacture dates about two centuries back, and it is said to have owed much of its extension to the measures of the unfortunate Wentworth in the reign of Charles I. The annual consumption of linen in England a century ago, was probably not far below that of her double population at present; owing to the very general substitution in our time of cotton articles. Then, as at present, the linen manufacture of England was established chiefly in Lancashire, in Cumberland, and in a county very remote from these—Dorsetshire. In 1745 government, apprised of the extension of the manufacture of coarse linen in Silesia and other parts of Germany, and actuated by the fallacious notion of making a monopoly of all kinds of productive industry, granted a bounty of 1½d. *per* yard on the export of all British linen of a value from 6d. to 18d. *per* yard; in other words, a premium of 20 or 25 *per cent.* on the prime cost of all inferior qualities exported. So large a grant soon augmented the manufacture of Osnaburgs and other coarse cloths, particularly in Scotland, although the ratio of increase was infinitely smaller than in the case of cotton, where there was no premium but a rapid improvement of machinery. The demand for bounty, in the ten years ending in 1785, was about L.33,000 annually. Since that time these impolitic issues have greatly increased, and of late years above L.100,000 has been paid for bounty on linen and canvas exported from England and Scotland.

The following returns from the Customhouse books show the extent to which we are dependant on foreign countries for a supply of the raw material; and on countries too which have linen manufactures of their own:

Linen Yarn.—Foreign imported into Britain in

	1814. cwt.	1815. cwt.	1816. cwt.
Russia, . .	5,780	323	220
Germany, . .	39,980	89,879	9,466
Other parts, .	166	994	5
	45,926	41,196	9,691

Flax Imported into Britain.

	1807. cwt.	1810. cwt.	1815. cwt.	1816. cwt.
Russia, .	372,000	478,000	20,000	9,000
Prussia, .	7,500	20,000	15,000	880
Holland, .	34,000	1,000	73,000	58,000
Other parts,				
	416,000	511,000	326,000	213,000

Into Ireland, on the other hand, the importation of foreign flax is almost nameless, seldom amounting to 100 tons.

The late war gave considerable vigour to our sail-cloth and cordage manufactures at Bridport, Lancaster, Workington, &c. the great source of supply was from Scotland; the manufacture of canvas for the navy having been carried on extensively in that part of the kingdom, particularly on the east coast. The average value of the linen of all kinds made in England hardly exceeds a million a year; and if we wish to contemplate this fabric in a state of extension and prosperity, our view must be directed to Ireland, where, without any aid from government, the manufacture of fine linen has continued progressively to augment, and has obtained the command of the market of England, reducing our imports from the Continent to a very small comparative proportion.

	Yards.
Average import of Irish linen into England for home consumption in the 12 years from 1800 to the end of 1812, . . .	32,800,000
Ditto from Germany, also for home consumption, about . .	2,000,000
Ditto from Russia, nearly . .	2,000,000

A similar superiority in favour of Ireland is proved by the Customhouse returns for years of peace.

	1814. Yards.	1815. Yards.
Plain linen of Germany and Silesia retained for home consumption, about . .	600,000	300,000
Russia, ...	2,300,000	330,000
Ireland, . . .	29,864,000	31,026,000

Having thus shown the mode of supplying the home consumption in the only great article of manufacture which England does not make for herself, we are next to convey an idea of our exports. This will be best done by two extracts from the Customhouse returns, the first for the linens of England and Scotland, exclusive of those of Ireland.

British Linens Exported.

To	1812. Yards.	1814. Yards.	1815. Yards.
Continental Europe,	4,328,000	2,807,000	980,000
E. Indies & Asia,	69,000	101,000	33,000
United States,	458,000	(war)	2 275,000
British N. America,	183,000	736,000	977,000
British W. Indies,	6,613,000	10,147,000	10,879,000
Foreign W. Indies,	1,789,000	4,255,000	1,510,000
Other parts, .	547,000	706,000	529,000
	13,987,000	18,752,000	17,183,000

(See *Customhouse Returns*, 5th April 1816.)

To these is to be added an export of canvas to the amount of about a million of ells annually, which goes chiefly to our North American and West India Colonies. The finer linens exported, viz. those above 10d. *per* yard, are not entitled to bounty. We come next to a more comprehensive table—to our linen exports generally.

Export of Linen Manufactures from Great Britain.

Years.	Value real not official.
1814, ...	L.1,732,691
1815, . . .	1,828,203
1816, ...	1,476,143

Of these a large proportion is of Irish manufacture.

It remains to add a few words in regard to the transit trade of England in foreign linen. This subject was, so lately as 1817, brought under the consideration of Parliament, and arguments of weight were offered for taking off the duty, collected for many years back on the German and Russian linen which passed through this country. Government, however, persisted in retaining it; less, in all probability, with a view to revenue, than to prevent foreign linens from rivalling British in the supply of our colonies.

Silk Manu-

In the silk manufacture, as in linen, we have had to contend with established manufacturers in other countries, particularly in France and Italy. We have had also to import the whole of the raw material. Such a manufacture was, therefore, unsuited to England, and would not have been attempted by our countrymen, but for the great profits expected from an article of general use, among the higher classes. Its introduction among us goes back to the fifteenth century. About the beginning of the seventeenth, it seems to have been carried to a considerable extent, owing certainly not to the luxury of the age, or to any great proportion of affluent persons in the community, but to silks being almost the only article of apparel in which the vanity of dress could display itself. Towards the end of the reign of Charles II., about the year 1680, raw silk began to be imported in quantities from India; and the English manufacture received a substantial addition by the numbers and ingenuity of the Frenchmen who settled in this country, after the revocation of the edict of Nantes in 1683. Various circumstances thus contributed to preserve, and even to extend the silk manufacture; and, as our rate of wages did not then materially exceed those of our neighbours, it seems to have experienced no great or general shock till the rivalship of cotton, after the surprising improvements introduced into that branch, between 1785 and 1795; but such was that rivalship, that it became in vain for the East India Company to increase their imports of silk, or to introduce, as they did at this period, into Bengal the Italian method of winding it. Nothing could counterbalance the cheapness and elegance of the new substitutes; and the weavers of Spittalfields became reduced to that penury, which, with few exceptions, has continued their lot ever since. It was a radical error to attempt establishing a great manufacture in London, where provisions, fuel, and house-rent, are necessarily higher than in the country. Accordingly, Coventry, Leek in Staffordshire, Macclesfield in Cheshire, Manchester, and other places, proved successful rivals to the metropolis. The present distress of the workmen in Coventry appears, by a very circumstantial exposition,* to be greater than has for some time existed in Spittalfields; but any superiority in the latter must be but temporary, and must arise from the operation of the poor's rate, or from the regulation of wages by act of Parliament.

The persons, young and old, employed in the silk manufacture in London, are computed at about 25,000; the number in all the provincial towns about 40,000; but the total value manufactured, in an article of such price, exceeds the proportion suggested by these numbers. It is calculated at L.4,000,000 Sterling a-year; an amount which is probably within one-fourth of the most flourishing state of the manufacture about the year 1785; and the magnitude of which, notwithstanding the general adoption of printed cottons, is chiefly to be accounted for from our augmented population.

The following years are selected to show the periodical variations in the supply of silk from different countries:

Years.	Raw Silk from Bengal.	Ditto from China.	From other Countries, chiefly the South of Europe.	Thrown Silk imported.
	lbs.	lbs.	lbs.	lbs.
1807	513,823	55,277	208,699	346,144
1809	164,100	90,603	443,486	501,746
1812	986,178	86,197	257,731	617,885
1816	764,663	88,987	92,142	192,130

Bengal has thus gained greatly over the south of Europe. In an article of such value for its bulk, the freight even from India is of little consequence; but there is another and a more substantial reason in the difference of duty. Raw silk from Bengal pays on warehousing only 5d. *per* lb., and 3s. 9d. additional when entered for home consumption; raw silk from China is taxed considerably higher; and that from other countries is no less than 5s. 6d. *per* lb. Each are entitled to a drawback, when re-exported in a manufactured state.

Export of Silk Manufactures from Great Britain.

Years.	Value, real not official.
1814, . . .	L.624,749
1815, . . .	6[illegible]2,929
1816, . . .	533,374

The chief vent for our silks is to our North American colonies, the West Indies, and Portugal; also to Ireland; but to the United States comparatively little, for we have never been able to rival the French in this manufacture.

The Leather Manufacture.

Leather, however little it may figure as an article of export, is necessarily one of extensive home consumption in every civilized country, particularly in such a climate as ours; and it is matter of regret, that we should have so very few *data*, official or otherwise, on which to form an estimate of the export or import of hides in former ages. Such an estimate would possess interest, as indicating the extent of our pasturage and the number of our cattle in comparison with our population. Whatever may have been the case at a remote date, the custom-house returns, for many years back, show, by the annual imports, that the demand for leather has exceeded the home supply of hides. For a long time this importation took place from the Continent of Europe, and from the least civilized quarters; from countries, such as Lithuania and Poland, where the quantity of hides furnished by the cattle materially exceeds that of the leather required by the inhabitants. But since the opening of South America, particularly in 1807, it has been found advantageous to import hides from that continent, where the herds of wild cattle are so numerous as to meet the eye of the traveller in almost every point of the horizon.

---

* Debate in the House of Commons, May 1819, on the state of the silk manufacture of Coventry.

Account of the Number of Raw Hides imported from various Countries into Great Britain during the years 1814 *and* 1815.

	1814. Number.	1815. Number.
Continent of Europe, .	148,730	161,362
Ireland, and the Isles Guernsey, Jersey, and Man, .	30,838	30,111
East Indies, . .	742	10,819
Africa, ...	55,885	56,962
America (chiefly South America),	541,979	783,171
West Indies, . .	46,031	20,460

The quantity of hides tanned in England and Wales is computed at nearly 9,000,000, weighing about 350,000 cwt. The largest tanneries are in Bermondsey in Southwark; but there are also very extensive establishments of the kind in the country,—in Cheshire, Lancashire, Westmoreland, Cumberland; also in Lincolnshire. The late war, by its long continuance, and the magnitude of our army and navy, produced great orders from government for our leather manufacture. Shoes were and still are made wholesale, in several towns of Staffordshire, Cheshire, and Northamptonshire. In this, as in other departments of manufacture, we suffer materially by our high wages, shoemaking on the Continent being considerably cheaper; but here also the spirit of invention has been active; and we have lately been informed, that, in the neighbourhood of London, machinery has been applied to what has hitherto been thought indispensably to require manual labour.

Of the annual value of our leather manufactured into shoes, boots, harness, saddlery, &c. there are no means of forming a correct estimate; but we have merely to consider the population of England, and the unavoidable extent of their wants, to be satisfied, that from ten to twelve millions sterling are rather below than above the mark. But while our home consumption is so considerable, our export is comparatively small, and does not exceed half a million sterling. To Ireland, the leather we ship is merely tanned; to other countries our exports are in a manufactured shape.

The increased duty imposed on leather towards the close of the late war, has been the subject of much discussion. This duty was brought forward in Parliament in the spring of 1813. It was evidently liable to the most serious objections, from increasing to the lower orders the expence of an indispensable article, and raising to farmers and others the price of harness and saddlery. Accordingly, the tanners, the leather-merchants, and the various classes affected by it, created an opposition which had well nigh defeated the bill. It was, however, carried, and has been continued without diminution since the peace. Its produce is nearly L.280,000 above the old tax, as is shown by a return from the Excise-office, dated 5th March 1818; from which it appears that the five last years of the old duty, viz. from 1807 to 1811, both inclusive, amounted to L.1,460,436

Five years of the new duty, leaving out the year 1812, and reckoning from 1813 to 1817, both inclusive, . 2,842,480

The Glove Trade. Connected with our general manufacture of leather is the Glove Trade, a branch of no inconsiderable extent, being carried on in several of our midland and western counties, viz. at Woodstock, Worcester, Ludlow, Hereford, Yeovil in Somersetshire, &c. The exports being chiefly to the United States, this branch of industry suffered severely from the war in 1813 and 1814. Nor has it by any means recovered its prosperity since the peace.

The Brewery. We come next to a branch of industry of a very different description—the Brewery. The amount of capital and labour, invested in brewing establishments in England, is very large, and particularly striking to those who have lived on the Continent, and have contrasted our situation with that of the wine countries of the south of Europe. It is only in Flanders and Germany that breweries are numerous; and in the latter, from the limited capital, and the scattered state of their population, there are hardly any of those large establishments which exist in our metropolis. In London, this important branch of business is chiefly in the hands of eleven great houses, who, conjunctly with the smaller establishments, brew on an average 1,700,000 barrels of porter. (*Excise Return*, 15*th May* 1818.)

Quantity of Barley made into Malt during Ten Years of War.

Years.	Quarters of Barley.
1804, . . .	2,817,285
1805, . . .	2,792,923
1806, . . .	3,435,990
1807, . . .	3,114,020
1808, . . .	2,800,787
1809, . : .	2,851,598
1810, . . .	3,035,401
1811, . . .	3,349,760
1812, . . .	2,332,336
1813, . . .	2,797,741
1814, . . .	3,263,785
—— . . .	2,962,875

In peace the average is comparatively higher in beer from the cheapness of barley, and in spirits from the exclusion of sugar from the distillery.—

Computing the whole barley made into malt in England in peace, at an average of . . .	3,300,000 qrs.
And supposing the distilleries in England to require . .	300,000
Remains for the breweries	3,000,000

Spirituous Liquors.

Spirituous liquors form one of the great branches of manufacture in which England is dependant on her neighbours; as she imports an annual supply of corn spirit from Scotland and Ireland, rum from the West Indies, and brandy from France. During the distress of the West India planters, particularly in 1807, 1808, and 1811, Committees of Parliament were appointed to inquire into the expediency of substituting sugar for barley in the distillery, and a great deal of useful information was the result of their researches. The consumption of British spirits in England was computed at

nearly . . .	5,500,000 gal.
Of which distilled in England nearly	4,200,000
Brought from Scotland, .	826,000
Ditto from Ireland, . .	470,000

(*Distillery Committee of* 1808, Evidence, p. 54.)

In the subsequent years Ireland fell off greatly in her supply of spirits, but Scotland, on the other hand, increased.

Spirits imported into England from Scotland and Ireland in the three years ending 5th April 1815, 1816, 1817. (*Return to Parliament,* 1817.)

Years.	Scotland. *Gallons.*	Ireland. *Gallons.*
1815,	1,748,351	428,933
1816,	1,360,380	283,621
1817,	1,262,539	20,069

Notwithstanding the great increase of distillation in Scotland, there seems to have been no diminution in that of England; the return of the excise duties from 1807 to 1815 being from L.1,500,000 to L.2,000,000, while the latest accounts, we mean those of the year ending April 1818 and April 1819, are far from indicating a diminution.

Of rum the consumption in England varies with the price of British spirits and several other causes, but averages from 2½ to 3 millions of gallons. (*West India Committee,* July 1807, p. 71.)

Import of foreign Brandy (stated in gallons) during three years of war.

Years.	France.	Spain.
1805,	2,663,000	405,000
1806,	1,418,000	263,000
1807,	2,167,000	156,000

Import into England of Rum, Brandy, and other Liquors (exclusive of Corn Spirits from Scotland and Ireland), in three years of Peace.

	Gallons.
In 1815, .	8,832,776
1816, .	7,966,052
1817, .	5,240,436

The Lesser Manufactures,—Glass, Hats, Pottery.

To the remaining manufactures our limits allow of little space, though several of them would be accounted of great importance in any other country than England. The extent to which such articles, as soap and paper, are made among us, is amply shown by the Excise Returns; but the list of our exports is of more consequence to the political economist; not from the vulgar notion, that it is by export only that national profit is realized, but as indicative of those commodities for which we possess, in our soil, our climate, or our colonial possessions, advantages that give us a superiority over our neighbours. Thus, in the case of glass, the abundance and cheapness of our coal outweigh our higher wages, and enable us to make an annual export of between L.600,000 and L.700,000. In the manufacture of hats, likewise, our command of wool for the coarser kind, and of furs from our North American colonies for beaver hats, enable us to ship to an extent of L.300,000, L.400,000, or L.500,000 a-year. In earthenware we have the advantage of clay, of fuel, and of ready communication by canals. These, joined to the taste and ingenuity of individuals engaged in the manufacture, carried it, in the course of the eighteenth century, to an extent that has rendered it a national object; a track of seven or eight miles in Staffordshire, called the Pottery District, being almost entirely appropriated to it. The population of this track is about 40,000. The great outlet is Liverpool, and the shipments take place partly to the United States, partly to the Continent of Europe. Our exports, comprising Porcelain, average from L.500,000 to L.600,000.

The stocking manufacture is carried on chiefly in the counties of Nottingham, Derby, and Leicester. It formerly employed vast numbers of women in knitting; but in this, as in other branches, machinery has greatly superseded manual labour. Lace is made in large quantities in the midland counties; and here also machinery has of late years been extensively applied. All its aid, as well as that of protecting duties, is necessary to maintain a competition with the neighbouring shores of the Continent, where lace-making is the chief employment of the females, and where a young manufacturer thinks herself sufficiently recompensed with sixpence a-day, while the pay of an experienced one seldom goes beyond a shilling.

General Observations and Tables.

After this account of particular manufactures, it remains to add a few general statements relative to this great department of our national industry. To point out those of our counties that take the lead as the seats of manufacture, we subjoin the following return:

Counties remarkable for Trade or Manufacture.	Number of Families so employed.	Return under the Property-Tax of Annual Profits from Trade, Manufacture, and Professions in these Counties.
		L.
Middlesex, . .	135,400	13,420,000
Surrey, includ. Southwark,	35,160	1,623,000
Yorkshire, . .	110,000	1,840,000
Lancashire, . .	114,500	1,800,000
Somerset, . .	23,700	1,296,000
Stafford, . .	34,000	495,000
Gloucester, . .	30,000	365,000
Nottingham, . .	19,000	310,000
Cheshire, . .	23,000	276,000
Durham, . .	17,000	237,000
Wales,—Glamorgan, .	8,000	132,000

Manufactures.

The whole number of *families* in England and Wales employed in trade, manufactures, and professions, was, by the return of 1811, 959,622. Their total income, L.32,210,600. To discriminate the persons engaged in trade from those engaged in manufacture, would not be easy; the above numbers being taken from the returns under the Population Act, which make no distinction between the two. The money return is for the year 1810, and indicates a rate of annual income, which, although below the vulgar estimate of mercantile profit, and considerably below the amount anticipated by Mr Pitt on first proposing the income-tax in 1798, is, we fear, above the actual rate of such profits at the present day.

An idea of the relative extent of capital and labour employed in each manufacture, will be best conveyed by the following table:

Excise Duties paid in Great Britain in the twelve months ending 5th April 1819, in British Produce and Manufactures.

British spirits,	L.3,210,959
Malt,	3,006,143
Beer,	2,718,018
Hops,	107,510
Licenses,	683,320
Salt,	1,518,498
Tobacco and snuff,	1,470,692
Soap,	845,627
Leather (hides and skins),	615,331
Glass,	497,611
Paper,	486,971
Printed goods,	433,902
Bricks and tiles,	319,571
Candles,	299,383
Starch,	51,241
Lesser articles of British manufacture, as vinegar, cider, &c.	88,959
Total of the excise duties from British produce and manufacture,	L.16,353,736
The remainder of the excise arises from public auctions,	267,070
Or from foreign articles, as tea,	3,097,746
Wine,	1,137,311
Foreign spirits (chiefly brandy),	2,159,922
Coffee and cocoa,	110,030
Total,	L.23,125,815

The above affords the best means of judging of our home consumption of manufactures: of our export, a collective view is given in the following table:

Manufactures.

Exports.

Exports from Great Britain.

	Year 1814. L.	1815. L.	1816. L.
Cotton manufactures,	17,393,796	19,127,266	13,078,794
Cotton yarn,	2,907,276	1,781,077	2,707,385
Woollen manufactures,	7,569,507	10,198,334	8,404,481
Iron and hardware,	3,442,332	5,468,318	4,892,924
Linen manufactures, chiefly Irish,	1,732,791	1,828,203	1,476,143
Silk manufactures,	624,749	692,929	583,374
Haberdashery and millinery,	500,034	603,585	498,040
Glass of all sorts,	658,871	779,070	782,770
Leather, wrought and unwrought,	573,639	582,821	403,236
Saddlery and harness,	81,907	126,112	115,854
Earthenware of all sorts,	463,900	716,222	637,201
Hats, beaver, and felt,	320,23	303,692	247,191
Hats of all other sorts,	144,318	115,179	69,098
Refined sugar,	3,260,444	2,942,042	2,153,476
Beer and ale,	315,869	384,534	351,007
Salt,	263,813	224,114	152,619
Lesser articles of produce and manufacture,	6,344,638	6,161,877	5,490,053
	46,598,015	52,035,375	41,994,546
It being customary to include our exported produce in the same return as our manufactures, we subjoin the former to complete the table.			
Coals and culm,	418,626	465,581	425,305
Beef and pork salted,	349,073	231,519	166,526
Fish of all sorts,	485,739	485,970	368,879
Total of British produce and manufacture,	47,851,453	53,217,445	2,955,256

We are next to compare these large sums with the inferior amounts of former years. The customhouse returns form here also our guide, and though our produce exported is included in the amounts, by far the greater part consists of manufactures.

Export of produce and manufacture from Great Britain, on an average of six years, ending with	1792,	L.22,131,000
Average of six years, ending with	1798,	25,658,000
Ditto, ending with	1804,	36,817,000
Ditto, ditto,	1810,	43,575,000

These sums are formed by adding 50 *per cent.* to the official estimate. In peace, a partial reduction takes place in the price of most merchandise, and we adopt a scale of valuation somewhat lower, by taking the value as declared by the exporting merchants.

Exports since the Peace.

Years.	Declared Value.
1814,	L.47,851,453
1815,	53,217,445
1816,	42,955,256
1817,	43,626,253
1818,	48,903,760

This is, of course, exclusive of the foreign and colonial merchandise exported each year.

Such are the principal facts in regard to the manufactures of England—the department of our productive industry which, of all others, has most conspicuously displayed the inventive powers of the hation, and most largely contributed to the unparalleled burdens of the late wars. In this age of rapid enhancement, manufactures present a striking exception to the general rule; for, while land, houses, fuel, corn, cattle, in short almost every thing else, has risen in price, manufactures have fallen, and fallen greatly. That this should have taken place in spite of the rise both of wages and materials, is to be ascribed altogether to mechanical inventions: the extent of which has been such as to render it not improbable that, in some fabrics, such as cotton, one person can now make, in a day, as such as, half a century ago, could have been made by a hundred. A writer, whose views, both on the practice and principles of trade, are entitled to attention,* has lately exhorted us to make a considerable change in our mercantile code;—to forbear all attempts at a monopoly of manufacturing industry, and direct our capital and labour altogether to those branches, such as hardware, woollens, and cotton, in which we possess local and permanent advantages. The principle of this reasoning is incontrovertible, but its practical application should be a work of great care and caution; for were we at present to throw open our ports to the import of goods manufactured abroad, our countrymen would emigrate by thousands to the Continent, for the mere purpose of labouring in untaxed countries for the supply of the British market.

VIII.—*Commerce and Shipping.*

Much of what relates to the *Commerce* of England has been already treated under the preceding section; and the colonial part of our trade shall be noticed in the next: At present, we are to exhibit a brief sketch of our commercial intercourse with Ireland and the Continents of Europe and America.

With Ireland, the intercourse of England is very great; that country sending us linen, cotton, salted provisions, and butter, to the amount of six or seven millions annually, and taking largely, in return, our manufactures, particularly cotton, woollen, and hardware.

North of Europe.—From Russia, our chief imports are hemp, flax, linen, timber, pitch, and tallow; from the Swedish dominions, iron and timber; from Poland, wheat, timber, and potash; from Prussia, wheat, timber, and flax. All these countries take our cottons, hardware, and colonial produce.

Central part of Europe.—From Holland, our imports are not foreign merchandise, as in the seventeenth century, when the Dutch were the carriers of Europe, but agricultural produce,—oats, wheat, seeds, hemp, cheese, butter; also gin; the whole to a large amount: in return for which the Dutch take our hardware, cottons, and woollens. From France, our imports have long been burdened with heavy duties; still they are large and increasing; consisting chiefly in wine and brandy, and, in a smaller degree, in silk and lace. With Germany, our chief intercourse is through the medium of Holland and Hamburgh. Our exports are large, particularly in cottons, hardware, and colonial produce. Our imports are very various, partly of corn, flax, timber, linen, and wine, from the vicinity of the Rhine.

South of Europe.—Here we enter on countries of much less industry. From Portugal we take wine in very large, and fruit in smaller quantities, in return for our cottons, our woollens, and hardware. From Spain, wool is the great commodity received; wine, brandy, oil, are imported in lesser quantities. Italy, without any commercial treaty, takes annually a portion of our manufactures, and gives in return silk, oil, and fruit. With the Levant, our traffic is similar, consisting in an export of manufactures, particularly printed cottons and hardware, and of an import of silk, fruit, and drugs.

The *United States* are, notwithstanding our political antipathies, our best customers, receiving from us manufactures of almost every kind, to a great amount, and sending us, in return, cotton, tobacco, rice, and flour. But the merchandise received from them being far inferior to the value of our exports, the difference is paid by remittances in money, from the Continent of Europe, arising from American merchandise sold there. With South America, a wide field of commercial intercourse will ere long be opened; at present, the chief articles received from that vast region are, cotton, hides, indigo, and cochineal. The trade is, and will long be, subject to the various disadvantages of a newly-settled country, bare of capital, deficient in industry, and possessing but a small number of consumers of European commodities in proportion to its extent and fertility.

Having, in the preceding section, given the exports of British produce and manufactures, it remains to give those of colonial and foreign produce. To convey an idea of the relative value of different articles annually exported from Great Britain, we select a particular year.

Export of Foreign and Colonial Produce in the year 1816.

Cotton, . . .	L.343,768
Hide raw and tanned, .	212,396
Indigo, . .	829,130
Logwood, . .	111,238
Pepper, . .	424,365
Piece goods of India, .	1,419,232
Rum, . . .	824,820
Sugar, raw, . .	1,594,685
Tea, . . .	546,701
Tobacco, . .	259,141
Wines, . .	220,789
All other articles, .	7,759,718
Total,	L.14,545,988

---

* *Observations on the Principles of the Commerce in Grain*, by Dugald Bannatyne, Esq. 1816.

Commerce, &c.

We shall next show the average annual amount since the beginning of the late wars.

Average of the Export of Colonial and Foreign Produce from Great Britain during periods of Six Years:

	Real Value.
From 1793 to 1798, .	L.10,756,875
—— 1799 to 1804, .	14,525,000
—— 1805 to 1810, .	13,012,916

To exhibit a comprehensive view of the export of both foreign and domestic merchandise, we add

Average of the Total *Exports from Great Britain in periods of Ten Years.*

	Real Value.
From 1761 to 1770, .	L.21,652,650
—— 1771 to 1780, .	21,173,700
—— 1781 to 1790, . .	27,769,100
—— 1791 to 1800, .	40,890,300
—— 1801 to 1810, . .	52,846,800

Since the peace, the total exports have been as follows; taking British goods at the value declared by the merchants, and adding, in the case of foreign or colonial goods, 25 *per cent.* to the official value:

Years.	Value real, not official.
1814, . . .	L.73,488,758
1815, . . .	74,371,819
1816, . . .	61,137,711
1817, . . .	58,032,406
1818, . . .	64,262,852

Proportion of our Exports sent to different parts of the World.

To exhibit this, we take the exports, not of recent years, in which commerce has experienced such rapid transitions, but of 1807, the last year during the war, in which neutral intercourse was undisturbed.

	Real Value.
To Ireland, . .	L.7,032,272
To the Continent of Europe,	15,420,514
To the East Indies and China,	3,555,392
To the Cape, and the rest of Africa,	1,022,745
To the United States, .	12,097,942
To the West Indies and other parts of America, . .	11,353,796
	L.50,482,661

For the distribution of our commerce in a year of peace, see the tabular statement of shipping for 1816.

Our imports excite much less attention than our exports, being apparently less intimately connected with that productive industry which affords a national surplus, and favours the popular notion of our extracting an annual revenue from our neighbours. They are, in general, from ten to twelve millions below the amount of our exports; a difference which was long, and still is, considered by many to indicate the amount of our annual gains; it being supposed that the excess of our exports constituted a favourable balance, which was remitted to us in money or bills of exchange. But money and bills of exchange are sent abroad as well as remitted, and had our metallic currency been in reality swelled by these successive importations during the last century, it would, ere this, have amounted to L.400,000,000 Sterling. The Bullion Committee of 1810, aware of the fallacy of this notion, and desirous to arrive at as great a degree of certainty as was practicable in so complicated a calculation, obtained from the Inspector-general of our imports and exports a computation, in an amended form, of the balance of trade. This estimate* exhibits an apparent favourable balance of L.8,000,000 or L.9,000,000 Sterling; but is evidently defective in some very material points, particularly in taking no notice of government remittances for garrisons abroad.

A list of bankruptcies forms an unpleasant part of our mercantile picture, particularly as their number is found regularly to increase with the extension of our commerce.

	No. of Bankruptcies.
In 1703, there were only .	30
1753, . .	214
1763, . .	233
1773, . .	562
1783, . .	528
1793, . .	1,304
1816, . .	2,442

If, as we believe, a large proportion of these failures has been owing to political convulsions, and to the indirect effect of the usury laws (See Art. COMMERCE, pp. 281, 282), we are not without hopes that settled peace, and a change in the laws in question, may materially improve this distressing part of our mercantile situation.

Shipping.

The following is a statement of the progressive increase of English Shipping.

Years.	Tons.
1663, . .	95,266
1688, . .	190,533
1701, . .	273,693
1715, . .	421,431
1737, . .	476,941
1751, . .	609,798

In the following years the shipping of Scotland is included:

1765,	726,402
1774,	901,016
1785,	1,074,862

We have selected years of peace, because in war the necessity of resorting to neutral flags generally causes a diminution of British shipping. The above column expresses the tonnage, not as permanently registered, but as entered in the Customhouse books on the outward clearance of vessels.

On coming nearer to our own times we possess more satisfactory documents; viz. the Tonnage and

---

* Appendix to the *Report of the Bullion Committee*, p. 228.

Seamen permanently registered in England, exclusive of Scotland, Ireland, and the Colonies, from the Customhouse returns on 30th September each year.

	Tonnage.	Seamen.
1792,	1,186,610	87,569
1800,	1,466,632	105,037
1812,	1,951,234	124,896
1813,	2,029,637	127,740
1814,	2,088,204	131,078
1815,	2,139,301	135,006
1816,	2,152,968	134,060

We add for one year (30th September 1817) the Total tonnage and seamen belonging to the British empire.

	Tons.	Seamen.
England, Scotland, and Ireland,	2,397,655	152,352
Guernsey, Jersey, and the Isle of Man, . .	23,689	3,190
Colonies, . .	243,632	15,471
Total,	2,664,976	171,013

Shipping in 1816.

Number of Vessels, with their Crews, which entered British Ports during 1816, *including their repeated Voyages in the course of the year.*

The West Indies, .	773	12,456	—	—
Spanish and Portuguese America,	190	2,093	4	85
Total of America, .	1,921	25,531	309	4,255
The Whale Fisheries,	175	6,774	—	—
Grand total,	16,754	119,779	2,825	22,253

The total of British shipping thus employed was nearly 2,000,000 tons; that of foreign nations only 318,000. The chief cause of this great superiority lies in our exclusive navigation to the East and West Indies; but as this proceeds in a great measure from our navigation laws, it is fit to look abroad and to compare our numbers with those of other nations in the comprehensive record kept in the entrance to the Baltic. The number of British vessels that entered the Sound in the year 1817 was 2088 out of 6758. In tonnage we bore a still larger proportion, perhaps the half of the whole, the majority of other vessels (Swedish and Prussian) being of inferior size.

As the preceding table does not include the coasting trade, we annex a computation of the number of vessels employed in that department of our navigation.

	Vessels.
From the whole of the Out-ports to the Port of London, ...	700
From Newcastle, Sunderland, and Blythe, with coals to London, . . .	450
Vessels in the Coal trade to other ports from ditto, ...	470
Vessels employed from Whitehaven and other ports in the Coasting Coal Trade, .	250
Vessels employed in conveying produce and merchandise to and from one Out-port in the United Kingdom to another, about	1130
Total,	3000*

Of these vessels the half in tonnage, if not in number, belong to the coal trade. Of the value of the merchandise or property thus transmitted, there are at present no means of judging; it being exempt from duty, and a great part of it either uninsured or covered in such a manner as not to come under the policy duty.

The shipping interest have long complained of the decay of ship-building, but an accurate inquiry was made in 1806, which showed, that whatever might be the case in regard to our southern dock-yards, the northern had increased their business, and that, on the whole, there was an augmentation. The returns made to government exhibit an instructive example of the migration of industry according to the price of living. The following Table shows a decrease:

	Tons of Shipping built in the two Years 1790 and 1791	Tons of Shipping built in the two Years 1804 and 1805
London,	16,372	12,680
Bristol,	3,071	1,623
Liverpool, .	6,710	4,154
Rochester, .	1,342	1,087

But the case is very different in the ports remote from the metropolis.

Sunderland, .	3,951	14,198
Hull, . .	8,193	10,839
Newcastle, .	12,444	15,054
Berwick, .	481	1,690
Whitehaven, .	3,630	6,750

---

* Colquhoun *on the Resources of the British Empire.*

Ship-building is carried on extensively in other ports, particularly at Whitby and Scarborough.

Total Tonnage of Ships built in Great Britain and Ireland.

	Vessels.	Tonnage.
1791,	720	65,000
1805,	740	80,000
1814,	706	86,075
1815,	913	102,943
1816,	851	84,676
1817,	758	81,263

Of this tonnage, about three-fourths is built in England, and the remainder chiefly in Scotland, very little ship-building having as yet taken place in Ireland.

IX.—*Colonies and Foreign Dependencies.*

The colonies and dependencies of England in the four quarters of the globe are,

EUROPE.

Guernsey,
Jersey,
Isle of Man,
Gibraltar,
Malta,
Heligoland.

AFRICA.

Cape of Good Hope,
Sierra Leone,
Cape Coast,
St Helena.

ASIA.

India,
Ceylon,
Prince of Wales's Island,
Bencoolen,
Isle of France,
New South Wales, or Botany Bay.

AMERICA.

Continent.—Canada, Upper and Lower,
New Brunswick,
Nova Scotia.
Islands.—Cape Breton,
St John's,
Newfoundland,
Bermuda.

THE WEST INDIES.

Jamaica,
The Leeward Islands,
The Windward Islands,
The Bohamas,
The Virgin Islands,
On the Continent.—Demerara, Essequibo, Berbice, Honduras.

North America.—Our exports to our North American colonies (see the account of CANADA, Vol. II. p. 599) vary from one to two millions Sterling. Our imports from Canada consist of furs and skins to a large amount. From Nova Scotia and New Brunswick the chief article received is timber; from Newfoundland, fish and seal skins. A great traffic is carried on between our West India and our North American colonies; the fish, flour, and staves of the one being exchanged in great quantities for the rum, the coffee, and the sugar of the other.

Shipping employed between Great Britain and her North American Colonies.

	Ships.	Tons.	Men.
1805,	288	52,412	2,707
1814,	392	81,939	4,277
1815,	672	145,448	7,241

West Indies.—*Imports into Britain from, and Exports to the West Indies, both in official value.*

		Vessels entered Inwards.		
Years.	Imports.	Ships.	Tons.	Exports.
1763	2,349,006			1,154,109
1773	2,836,093			1,335,773
1783	2,891,805	614	124,239	1,796,982
1793	4,392,158	689	156,962	2,695,220
1798	5,411,962	637	163,399	5,197,913
1803	6,040,067	614	180,950	2,344,647
1808	8,716,918	805	228,082	5,850,773
1814	8,200,506	685	212,776	6,284,353
1815	8,371,193	701	223,246	6,862,371
1816	7,428,617	680	219,042	4,559,665

The most remarkable fact in this table is the increased dimensions of the vessels; the average size of a West Indiaman, which, in 1783, was only 200 tons (registry) being now fully 320. The revenue arising from our West India imports is five millions annually, of which about three millions are from sugar; the rest chiefly from rum. The trade of these colonies has been exposed, particularly in the years 1806, 1807, 1808, and 1811, to the most distressing fluctuations. At the peace of 1814, Surinam was restored to Holland; but Demerara, Berbice, and Essequibo, remain to Britain, with certain provisions in favour of the Dutch proprietors of plantations. They are at liberty to send their produce to Holland, and to receive from that country the stores or other articles of supply necessary for their estates; but they are not allowed to import Dutch commodities for sale.

East Indies.—*Average of Exports from England to India (exclusive of China), on a series of Six Years, from 1806 to 1811.*

On account of the East India Company, . . .	L.1,371,666
——— of private merchants trading to India, . .	453,666
of the captains and officers of the Company's shipping,	418,333
	L.2,243,665

This includes the specie exported, which, however, was to a small amount. The value of goods imported from India is increased by the freight, interest of money, expected profit, &c.; and, though very fluctuating, might be averaged previous to 1814 at L.800,000 Sterling; and the seamen employed, at 6000. But since the trade has been laid open, speculations have been entered into from Liverpool, Bristol, and other ports, which have greatly altered the aspect of this branch of our commerce, and put all correct calculation out of the question. The exports are increased to a degree which cannot continue, as British merchandise has for some time sold in India considerably below prime cost.

Tonnage of Shipping cleared outward to the East Indies.

	1815.	1816.	1817.
From London, .	78,431	87,866	85,172
—— Liverpool and other ports in Britain, .	1,549	10,655	19,456
	79,980	98,521	104,628

(Customhouse Return, dated 1st May 1818.)

China.—This branch of trade remains in the exclusive possession of the East India Company. Our annual exports, from L.1,000,000 to L.1,200,000, are chiefly of broad cloth: our imports consist of tea in vast quantities; also of nankeens and raw silk. This trade employs nearly 20,000 tons of shipping, and 2000 seamen. (See the Article CHINA in this *Supplement*, Vol. III. p. 108.)

X.—*Establishments for Religion and Education.*

Rank of the Clergy.

The Church of England has two archbishops and twenty-four bishops; all peers of the realm, and all indebted for their appointment to the Crown. The bishop of the Isle of Man is appointed by the Duke of Athol, and has no seat in the House of Lords. The province of York comprises four bishoprics, viz. Durham, Carlisle, Chester, and the Isle of Man; all the rest, to the number of twenty-one, are in the province of Canterbury. The clerical dignitary next to the bishop is the archdeacon, whose duty, though very different in different dioceses, may be termed that of a representative of the bishop in several of his less important functions. The number of archdeacons in England is about sixty. The name of Dean *(Decanus)* was probably derived from his originally superintending ten canons or prebendaries. Each bishop has a chapter or council appointed to assist him, and each chapter has a dean for president; but there are in the Church of England many deaneries of other descriptions. Rector is, in general, the title of a clergyman holding a living, of which the tithes are entire; vicar is understood of a living where the great tithes have passed into secular hands. The very general name of curate signifies sometimes (as *curé* in France) a clergyman in possession of a living, but more frequently one exercising the spiritual office in a parish under the rector or vicar. The latter are temporary curates, their appointment being a matter of arrangement with the rector or vicar; the former, more permanent, are called perpetual curates, and are appointed by the impropriator of the tithe in a parish which has neither rector nor vicar. The name of priest is, in general, confined to the clergy of the church of Rome; in the church of England, the corresponding term is a "Clerk in Orders." A parson *(parsona ecclesiæ)* denotes a clergyman in possession of a parochial church. Deacon is, in England, not a layman, as in Calvinist countries, but a clergyman of limited qualifications, entitled to preach, baptize, marry, and bury, but not to give the sacrament. "Readers" are not regular clergymen, but laymen of good character, licensed by the bishop to read prayers in churches or chapels where there is no clergyman. See Adolphus *on the British Empire*, Vol. I.

A clerical education in England is of much less length than in Calvinist countries; in Scotland, Holland, Switzerland, or the North of Germany, after going through a course of classics and philosophy, a second course is required for theology solely, but in England the former is sufficient. The degree of bachelor of arts requires an examination and a university residence of three or four years; but to qualify for the acceptance of a curacy, a certificate of attending a single course of lectures in divinity is all that is necessary.

Livings.

The number of church livings in England and Wales is very great, being fully 10,500. From this multiplicity of benefices, and from the general smallness of the incomes, have arisen two irregularities,—pluralities and non-residence,—both forbidden by the ancient statutes of the church, but both long sanctioned by usage. Many clergymen hold livings without doing duty at any of them; others do duty in one or in two that are adjacent to each other, and have a curate for the more distant; while curates frequently do duty at two and sometimes at three distinct places of worship. To prevent, or at least to lessen the abuse of non-residence, an act of Parliament was passed in 1813, directing that every non-resident incumbent should nominate a curate at a salary of not less than L.80 a-year, unless the entire living should be less. The effect of this act was to reduce the number of non-resident clergymen by 800 fully; they had previously been about 4700; but in 1815, the official return to Parliament of the incumbents in England and Wales was as follows:

Non-resident from the following causes:

Sinecures, ...	52
Vacancies, ...	164
Sequestrations, ...	40
Recent Institutions, ...	87
Dilapidated Churches, ...	32
Held by Bishops, ...	22
Law-suits, absence on the Continent, &c.	122
Livings from which no report, . .	279
	798
Incumbents non-resident from other causes,	3,856
Incumbents resident, ...	5,847
	10,501

The rental of England and Wales was, by a late return, discriminated as follows in regard to tithes:

Tithes.

Tithe free *in toto*, . . .	L.7,904,379
Tithe free in part, . . .	856,185
Free on payment of a *modus*,	498,823
Subject to tithe, . .	20,217,467
Total,	L.29,476,854

A part, and by no means an inconsiderable one, of the tithes of England, is held by laymen; but as the church has other sources of income, its total revenue is computed at nearly L.3,000,000; but the absorption of large sums by several of the prelates (as the Bishops of Durham, Winchester, and London), and the accumulation of the best livings among a few individuals of influence, reduce the annual average income of the curates, or most numerous class, to little more than L.100 a-year.

Tithes necessarily fluctuate with the state of agriculture, and, during the distress of 1815, the deficiency in this respect became alarming. It was then that the clergy felt what they should have felt long before, that tithe was an unsuitable and impolitic source of revenue. Application was made to Parliament, and the subject was for some time under serious discussion; but the rise of corn, in 1816 and 1817, prevented any other measure than an act founded on a Committee Report of 18th June 1816, authorizing the possessors of tithes (laymen as well as clergymen) to grant leases of them for a term not exceeding fourteen years.

A late return to Parliament (June 1817) specifies the incomes of those benefices where there is no parsonage-house, or at least none that forms a suitable residence.

	Livings.
From L.10 to L.100, . . .	615
100 to 150, . . .	442
150 and upwards, . .	793
	1850

Churches.

A prior and more comprehensive return had stated the number of churches and chapels for the established faith at 2533; and as these were inadequate (the members of the established church being about five millions, or half the population of England and Wales), an act was passed in 1818, and even pecuniary aid given by government, for the erection of a number of additional churches. The previous attempts to raise the requisite funds by the issue of briefs and voluntary subscriptions, had exhibited a miserable specimen of misapplied labour; the expences of the collection, and of the patent and stamps, absorbing more than half the money received from the subscribing parties.[*]

Clerical Terms.

A prebend is a provision in land or money given to a church in *præbendum*, that is, for the support of a clergyman whose title may be either prebendary or canon. Advowson (*advocatio*) is the right of presentation to a living, and was first vested in those laymen who were founders of, or benefactors to livings. A living is held *in commendam* when, to prevent its becoming void, it is committed (*commendatur*) until conveniently provided with a pastor. *Modus* (*modus decimandi*) is a composition for tithes; it may be either perpetual, or during the lives of the contracting parties. The lay impropriators of tithe, so frequent in England, date from the dissolution of monasteries in the reign of Henry VIII.; patrons were then allowed to retain the tithes and glebe in their own hands, without appointing a clergyman; in cases of such appointment, the clergyman was called *vicarius*, or representative of the patron.

Dissenters.

The dissenters in England are, first, the Presbyterians, who nearly coincide with the Church of England as to doctrine, but differ in church-government, allowing no hierarchy in individuals; next the Independents, who go farther, and disclaim hierarchy in synods and other collective assemblies; the well known sect of Quakers date from the middle of the seventeenth century; the more numerous Methodists from 1729. Of the Anabaptists, the chief characteristic is their not receiving baptism till they become adults. The Catholics in England are not numerous, but comprise a large proportion of wealthy families. The Test Act declares that no person can be legally elected to a public office unless he be a member of the Church of England; but an act of Parliament is annually passed to indemnify all persons who shall not have complied with the requisitions of the Test Act.

Education.

In regard to the mode of education in England, there is much both to commend and censure. Scotland has been for a century past in possession of a larger proportion of parish schools; but the utility of these is much lessened by an established routine of teaching Latin to almost all youths, whatever be their intended line of life. In England this absurdity is less prevalent, because most of the schools are private undertakings, the managers of which are necessarily guided by considerations of utility. The youth destined for a life of business are thus saved a serious waste of time; their education, if imperfect, is not supererogatory; but, on examining the higher seminaries of England, we find much ground for disappointment, and many marks of a blind adherence to ancient usage. Two universities are evidently inadequate to the education of the nobility, the gentry, and the clergy of so populous a country. Their course of study, also, is quite unsuitable to the future occupations of many of the students. They were originally designed for the education of churchmen; and, to this day, Latin and Greek, with the addition of mathematics at Cambridge, form the chief objects of instruction. In a country of which commerce forms the strength, there are no teachers of political economy. Under a government which has so long borne the representative form, there are no classes for the study of modern history, or the principles of legislation. There are here hardly any of those public lectures, which, in the rest of Europe, constitute the grand characteristic of a university, and distinguish it from schools:—all, or nearly all, is done by private tuition. Each college has two, three, or more tutors (appointed from among the fellows), who receive in their rooms the students at stated hours, and read Greek or Latin with a class, which, in Oxford, rarely exceeds half a dozen at a time. Again, in point of constitution, while in other countries a university forms, in general, one large association, in England each college is a distinct body, having its head, its fellows, and its students, who, as far as education is concerned, have very little connection with the rest of the university. It is, doubtless, this insulation, both as to study and discipline, that has prevented the formation of public classes, and been the cause of the very uniform and limited course followed both at Oxford and Cambridge. In one point, however, these venerable seminaries redeem their faults, and assert the dignity of their character;—we mean in their public examinations. These, since the early part of the present century, have been put on an admirable footing, both at Oxford and Cambridge; distinguishing the relative degrees of proficiency with great accuracy, and converting into a full and impartial trial that which in other universities is almost always a mere form.

---

[*] See *Return of Briefs delivered to Parliament*, 19th May 1819.

No country rivals England in the magnificence of her academical buildings. While in France, Germany, or Holland, a university possesses only a single pile of building, Oxford and Cambridge can boast for every college a large, commodious, and generally an elegant structure. The endowments appropriated to them are very various, both in their origin and destination, but they arise chiefly from land, and, having increased with the rise of rents, are in many cases very ample. The destination of these funds is regulated by the bequest of the donors, and the established usage of the colleges; part going to students, under the name of exhibitions or scholarships: part to the head and fellows; and a farther part, consisting in livings, which devolve in succession on the fellows, and lead to their removal from the university. The number of students has of late been considerably on the increase in both universities; but the public lists retaining the names of many who have long left college, the number actually engaged in a course of study does not exceed 2500, taking Oxford and Cambridge together. A hall is an inferior college; an academical establishment not incorporated or endowed, but possessed of exhibitions or other provisions for students. Oxford has nineteen colleges and five halls. Cambridge twelve colleges and four halls.

Boys in England are taught the classics, either in the lesser schools, established at every town of consequence throughout the kingdom, or at the great public schools. Of the latter, the principal are Eton, Westminster, Winchester, and Harrow; also the Charter-house, St Paul's, and Merchant Taylor's school. These seminaries, at present so expensive, and attended by youths of the first family, had their origin in a fund or provision, set apart for scholars of humbler birth. This has served as the basis of a stately superstructure, each school having attracted, by the advantage of situation, or the repute of the teachers, a much greater number of pupils in independent circumstances. But in each a proportion of the scholars are still on the foundation. At Eton there are 70 thus provided for; at Winchester the same number.*

Education of the Poor.

On the education of the poor, a great deal of useful information has been lately laid before the public, by the Reports of the Committee appointed to "inquire into the education of the lower orders;" at first in London, afterwards throughout England at large. The earliest of these Reports, dated in June 1816, contains various statements of the proportion of the poor, who are destitute of the means of instruction. In the neighbourhood of Covent Garden, the proportion was 679 uneducated out of 829. In Southwark, of 12,000 children between the age of five and fourteen, 6000 were unprovided with the means of instruction; but of all ignorant and abandoned districts, St Giles is beyond comparison the worst; containing more than half the Irish in the metropolis, whose children, in number about 3000, were not only uneducated, but trained, after the age of seven or eight, to habits of begging and thieving. Elementary schools were not absolutely wanting in London, nor was the price of admission unreasonable; but the want of decent clothing was, in very many cases, the cause of not sending the children thither. The whole number of children in the metropolis, unprovided with education, was computed at more than 100,000; and in all England, the number is certainly not overrated at 500,000.

The efforts of the *National Society*, as Dr Bell's adherents term their establishment, make a very conspicuous figure in the evidence annexed to these *Reports*. The amount subscribed from 1811, the time of its formation, to last year, was (*Second Report*, p. 10) about L.40,000; the chief part from occasional donations, the annual subscriptions amounting only to L.1500. This society, though it has established only one great school, that of Baldwin's Gardens, in Gray's Inn Lane, has contributed to the erection or enlargement of more than 200 schools, by pecuniary grants, varying from L.15 to L.100, and amounting, in particular cases, to L.200, and even L.300. Above 500 teachers, male and female, have been trained on Dr Bell's plan, and the number of children now receiving education on this system is between 150,000 and 200,000, distributed over more than 1000 schools in all parts of the kingdom. Of these, the greater part have adopted Dr Bell's plan, without receiving any other aid than a supply of elementary books. The conditions required by the Society in return for

---

* *Reports of the Education Committee*, 1817 *and* 1818.

Establishments for Religion, &c.

their aid, were, that the liturgy and catechism of the Church of England should be followed, and that no religious tracts, except those sanctioned by the *Society for Promoting Christian Knowledge*, should be admitted into the schools. The Society, however, is by no means illiberal, extending its instruction to children of all denominations, even Jews (*Report First*, p. 32), and allowing dissenting pupils to attend divine service in the place pointed out by their parents. In regard to expence, though not so small as asserted in some extreme statements which have gone abroad, nothing can be more gratifying than to find that, even in the opinion of the witness disposed to rate it at the highest, it does not exceed (*Evidence*, p. 268) 12s. *per* head *per annum*. One master, with the aid of monitors, can superintend 500 scholars.

The British and Foreign School Society, for that is the name adopted by the supporters of the Lancasterian plan since their separation from its founder, without possessing such extensive support as the *National Society*, have been extremely liberal and active; having collected above L.20,000 previous to 1816, and having expended considerably more; the trustees advancing the balance from their own property. Among other supporters, this Society reckons one who conceals his name from all but the treasurer, and who has already come to its aid with the large sum of L.3000! The original and central school of this Society is in the Borough Road, Surrey. The number of Schools throughout the kingdom for boys and girls is supposed to exceed 400, having, on an average, from 150 to 200 pupils. The expence of the Society in aiding schools, and still more in training male and female teachers, is between L.2000 and L.3000 a-year.

Until these benevolent establishments were disseminated, the principal means of instruction for numbers of the poor were in the *Sunday Schools;* an institution highly advantageous, in preventing an improper observance of Sunday, but necessarily of very slow effect in the business of teaching. The number of Sunday scholars in the metropolis is computed (*First Report*, p. 76) at 40,000; but the time required there by a child to learn to read extends to two, two and a half, and even to three years. The *Society for Promoting Christian Knowledge* is of old date, having been founded in 1698. Its object is to assist parish schools which belong to or are not adverse to the Church of England, with books at a very reduced price, about half the prime cost. The funds arise partly from money in the stocks, partly from voluntary contribution. The annual income and expenditure exceed L.40,000.

The Education Committee brought its labours to a close in a *Third Report*, dated June 1818. Their concluding observations were, That the discussion excited by the inquiry had greatly improved the administration of institutions for the education of the poor; but that much remained to be done; the efforts of private benevolence being almost entirely confined to towns, and the aid of government being wanted in the thinly peopled districts, to the extent, at least, of the purchase or erection of a schoolhouse, leaving the annual expence to be defrayed by private subscriptions. The Committee recommend farther, a connection between such schools and the Established Church, although, in England, this is a matter of greater difficulty than in Scotland, where, in point of doctrine, the dissenters differ very little from the Establishment. In regard to the anxiety of the poor for the education of their children, there is, say the Committee, the most unquestionable evidence that it is not only unabated, but daily increasing.

Charitable Establishments.

XI.—*Establishments for purposes of Charity.—Poor-Rates.*

The public charities of England are very numerous; the bequests of benevolent founders in this country exceeding those of the zealous Catholics of France or Spain, as well as those of the once affluent Protestants of Holland. Our limits admit of the notice of only a few of the foundations in the metropolis and its neighbourhood.

Among the principal *Hospitals* are,

Bethlem Hospital.
St Luke's, Old Street.
St Bartholomew's, West Smithfield.
Guy's, in Southwark.
The Lock Hospital, Hyde-Park-Corner.
The London Hospital, Whitechapel Road.
The Magdalen Hospital, St George's Road.
The Middlesex Hospital, Berner's Street.
The Foundling Hospital.

Among the *Dispensaries* and medical charities are.

The General Dispensary, Aldersgate Street.
City Dispensary in the Poultry.
Finsbury Dispensary.
Various Vaccine Dispensaries.
The Fever Hospital, instituted in 1801.

A *College*, in the sense of a charity, is an almshouse on an enlarged scale, under the direction of a master and other incorporate officers. There are only three in the neighbourhood of London, viz. Bromley, Morden, and Dulwich Colleges.

Alms-Hou[illegible]—These are very numerous, viz. the Haberdashers', Mercers', Skinners', East India Company's, &c.

School Charities.—These also are very numerous. Among the most remarkable are,

Christ's Hospital, or the Blue Coat School.
Marine Society.
School for the Indigent Blind.
Deaf and Dumb Asylum.
Debtors' Children.
Ladies' Charity School.
Masonic Charity.
Raines's Charities.

Miscellaneous Charities.—Under this head are comprised several extensive and well known associations.

The African Institution.
The British and Foreign Bible Society.
Society for Bettering the Condition of the Poor.
Society for Promoting Christian Knowledge.
The Missionary Society.
The Literary Fund.

Poor Rates.

We must next advert to a much more serious subject,—to the consideration of a tax, which, of all the burdens of England, is perhaps the most oppressive, Charitable Establishments.

we mean that levied for the *Poor*. The discussion, in a politico-economical sense, must be deferred till we treat of the POOR-LAWS. At present we can exhibit only the principal returns and calculations, none of which, that are at all complete or accurate, go farther back than the middle of the last century.

The following table shows the expenditure on the Poor of England and Wales, making the year close at Easter, and adding the corresponding average price of the bushel of wheat.

			Wheat.
1748, 1749, 1750,	average	L. 692,000	4s. 5d.
1776,	.	1,566,000	6s. 9d.
1783, 1784, 1785,	average	2,010,000	7s. 7d.
1803,	.	4,268,000	8s. 1d.
1813, 1814, 1815,	average	6,147,000	12s. 8d.

The amount of expenditure in each tenth year, calculated from the above, together with the price of wheat, will stand thus:

		Wheat.
1750,	L. 713,000	4s. 2d.
1760,	965,000	4s. 10d.
1770,	1,306,000	6s. 5d.
1780,	1,774,000	5s. 11d.
1790,	2,567,000	6s. 4d.
1800,	3,861,000	10s. 2d.
1810,	5,407,000	12s. 4d.

The sums of expenditure are taken from the *Second Report on the Poor-Laws* (March 1818), and the price of wheat is added, because the well known rule of English parishes, in affording relief to the poor, is to proceed on a conjunct calculation of the price of bread and the number of children in a family.

The following table shows the proportion of the wages of the country labourer to the price of corn. (Barton *on the Labouring Classes*, published in 1817.)

Periods.	Weekly Pay.	Wheat *per* Quarter.	Wages in Pints of Wheat.
1742 to 1752,	6s. 0d.	30s. 0d.	102
1761 to 1770,	7s. 6d.	42s. 6d.	90
1780 to 1790,	8s. 0d.	51s. 2d.	80
1795 to 1799,	9s. 0d.	70s. 8d.	65
1800 to 1808,	11s, 0d.	86s. 8d.	60

These statements exhibit in the enhancement of wheat one very considerable cause of augmentation of the poor's-rate.

We now come to returns of later date; the result of the researches of the *Committee on the Poor-laws*, whose first and most comprehensive Report was made to Parliament in July 1817.

Return of Poor-Rates from London, Westminster, and Southwark, being from the Parishes within the Bills of Mortality, delivered to Parliament 21st February 1817.

	Year ending Easter 1813.	Easter 1814.	25th March 1815.
	L.	L.	L.
Total raised in the metropolis by poor's-rate, and smaller rates, such as church-rate, highway-rate, &c.	446,542	501,952	489,321
Charitable donations for parish schools and other purposes,	18,983	19,620	20,160
Expenditure.			
Relief and maintenance of the poor,	L.370,518	401,954	380,281
Lawsuits, removals, expences of overs[illegible] other officers,	15,324	17,416	17,433
Families of militia-men,	12,916	10,837	6,613
Church-rate, highway-rate, county-rate, &c.	98,903	113,574	103,807

Number of Persons relieved by this Expenditure.

Poor permanently relieved in workhouses,	97,223	94,085	88,115
Do. do. out of workhouses (without reckoning children),	434,441	430,140	406,887
Parishioners relieved occasionally,	440,249	429,770	400,971
Total of paupers relieved,	971,913	953,995	895,973

The property liable to poor's-rate consists of the land and houses of England, the annual rent of which, under the latest estimate, is	L.51,898,424
Deducting for various allowances and abatements, the fractional sum	1,898,424
Remains,	L.50,000,000

The average poor-rate on which, for the three years in question, is 3s. 4d. *per* pound. In general, the computation is made differently, and at so many shillings not *in* but *on* the pound,—thus 20s. on the pound would be half the actual rent. Sussex, the county the most burdened with poor-rates, paid 7s. 8d. *on* the pound in 1813.

The number of persons receiving parish relief in England is beyond example in any country or any age, being fully one person in eleven, if we compute by the above enumeration; and many more (not less than one in eight), if we comprise the children of the 400,000 or 500,000 persons who receive permanent relief at their homes. The workhouse plan is adopted in the case of nearly 100,000 individuals. Its extension was in a great measure owing to an act passed in 1782, commonly called Mr Gilbert's Act, which, to obtain the advantages arising from a collective assemblage of the poor, from a joint management of disbursement and a considerable division of labour, empowered the magistrates to consider any large workhouse as a common receptacle for the poor throughout a diameter of 20 miles. As yet this plan has by no means been successful. Proper care has seldom been taken to separate the inmates of the workhouses according to their age or their habits; nor has the division of employment been carried to the necessary length. The four shillings a-week, which each pauper generally costs in a workhouse, is much more than would have been requisite at their own habitations.

Scotland was originally subjected to a similar system for the poor, but fortunately escaped its perversion, from the execution of the law being vested, not in temporary officers, such as church-wardens and overseers, but in the landholders, ministers, and elders, whose personal acquaintance with the poor enabled them to act with discrimination. It would be no small improvement in England to appoint, as overseer, a permanent officer with a salary, to act, if necessary, for more than one parish, a practice already adopted in some cases with success. The landed interest complain that the burden of the poor's-rate falls exclusively on them and the owners of houses. But there are strong objections to imposing any part of this burden on the income of the stockholders or the profit of traders. (*Report on the Poor Laws*, 4th July 1817, p. 6.) There would be no check to a perpetually increasing disbursement were the burden to be rendered national instead of parochial. Nor is it true that the trading and manufacturing districts have increased their paupers in a greater proportion than the agricultural. In Bedfordshire and Herefordshire, the two counties which employ the largest proportion of their inhabitants in agriculture, the same progressive augmentation of assessment has taken place. (See *Report on the Poor Laws*, 1817, p. 8.)

	Expended on Paupers in 1776.	Average Expenditure of 1783, 1784-5.	In 1808.	In 1815.
Herefordshire,	10,593	16,728	48,067	59,256
Bedfordshire,	16,663	20,977	38,070	50,271

The consideration of most importance, as connected with the landed interest, is the reciprocal effect of the poor and the corn-laws; if the latter afford the landholders an indemnity for the extra burden of the former, the public may fairly claim a proportional reduction of the importation limit of corn in return for such alleviation as may be made in the pressure of the poor-rates on the land. This idea, at which our limits permit us only to hint, might, in our opinion, be made the basis of the most beneficial regulations. A great proportion of the present poor's-rate has arisen from the voluntary conduct of the more affluent classes, who, during the war, preferred paying an extra charge to raising the wages of country labour. This was shown by the remarkable fact of such labour being considerably cheaper in England than in Scotland. An effectual reduction, therefore, can take place only in two ways; either by raising wages as parish relief is withdrawn, or by approximating the personal expences of our poor to that of the poor of the rest of Europe, by a progressive abrogration of the corn-laws.

Friendly Societies.—These associations are spoken of with much commendation in the *Reports of the Committee on the Poor Laws.* We extract the number of members.

XII.—*Establishments for the Purposes of War.*

The establishments both for the Navy and Army have, in the present age, been carried to an extent of which no country has exhibited an example. Greater efforts, perhaps, have been made on sudden emergencies, both in ancient and modern times; but neither Prussia, the most military state on the Continent, nor France in the reign of Buonaparte, could stand a comparison during last war with England in the proportion borne by her armed force to the population at large. The difficulty lay, not in levying every tenth, or even every eighth man in a courageous population, but in finding, from the public credit and the productive industry of the rest of the community, the means of supporting so vast a number "in arms and idleness" during a succession of years.

Annual expenditure for our Navy, Army, and Ordnance during last War, from the Returns to Parliament.

Years.	Navy.	Army.	Ordnance.
1803	7,979,878	11,299,406	1,827,049
1804	11,759,351	15,744,694	3,550,141
1805	14,466,998	17,019,728	4,732,286
1806	16,084,027	15,111,490	4,511,064
1807	16,775,761	15,208,550	4,190,748
1808	17,467,892	17,201,061	5,108,900
1809	19,236,036	18,463,094	4,374,184
1810	20,058,412	18,536,299	4,652,331
1811	19,540,678	23,869,359	4,557,509
1812	20,500,339	24,987,362	4,252,409
1813	21,996,624	29,469,520	5,404,527
1814	21,961,566	33,795,556	4,480,729
1815	16,373,870	23,172,137	3,736,425
Total during 12 years of war,	L.207,827,562	240,706,119	49,641,877

The navy expenditure increased very gradually; that of the army took a sudden rise in 1812 and 1813, owing, in part, to our increased scale of exertion in Spain, but more to the unfortunate fall of the exchanges, which, in these years, were nearly 30 *per cent.* against us. These returns refer, of course, not to England alone, but to the United Kingdom at large. The numbers maintained in the latter years were, in the navy, 140,000 seamen and marines; in the army about 300,000; viz. in regulars and in foreign corps, exclusive of our troops in India, 207,000; in regular militia, 93,000; the whole effective, and without reckoning a very numerous force of local militia, occasionally embodied. In 1814, a great reduction took place, particularly in the navy. In 1815, the alarm caused by Buonaparte's return suspended for a time the reduction of the army, but, in 1816, there were nearly 37,000 discharges, exclusive of 10,000 deaths and desertions. Still we had, in 1817, a force abroad and at home, of nearly 20,000 cavalry, 6000 foot guards, and 115,000 infantry. The expence of nearly 50,000 of these troops was defrayed by France and the East India Company; for the remainder the following sums were voted by Parliament:

Abstract of the Army Estimates for 1817, exclusive of the Extraordinaries of the Army.

	Annual Charge.
Land forces (exclusive of those serving in France and India), 92,282 officers and men, . .	L.3,351,377
Staff officers, . .	146,816
Public departments, . .	163,104
Medicines, &c. . . .	26,446
Volunteer Cavalry, . . .	106,665
Additional pay to general officers who are not Colonels of regiments, .	179,045
Full pay of those officers who have retired on that condition, . .	132,536
Total half-pay and allowances to other officers, . . .	813,012
Pensions to subalterns and privates,	1,009,530
Widows' pensions, . .	98,984
Compassionate list, and pensions for wounds, . . .	163,502
Garrison charges at home and abroad,	34,078
Military college (Sandhurst), .	23,155
Military asylum (Chelsea) for soldiers' children, . . .	34,415
Superannuation allowances, adjutants of Local Militia, and Exchequer fees,	80,067
	L 6,367,732

Since 1817, a farther and very large reduction has taken place, particularly in the course of 1818 and the present year. The peace establishment, exclusive of the troops of India, is at present fixed at 8954 cavalry, 5760 foot guards, 55,090 infantry; making a total of 69,794. This is considerably beyond the peace establishment of 1792; and in consequence of the large sums issued for the half-pay of officers and the pensions of privates, the expenditure is still very great, being computed by the Finance Committee (*Second Report in* 1819) at L.6,380,000 annually; to which is to be added a charge, varying from year to year, but hitherto very heavy, under the head of "Army Extraordinaries." The infantry now consists of only 93 regiments; the light dragoons of 19. During the war, there were 33 regiments of light dragoons, and 135 regiments of foot, many of them of two battalions. An extra proportion of our military are at present stationed in Ireland, to prevent illicit distillation and other frauds on the revenue. In India, our force consists of about 20,000 King's troops and 8000 Company's, all Europeans, and exclusive of 150,000 natives; the whole are in the pay of the East India Company.

Navy

The progressive increase of our naval force in-

Establishments for the Purposes of War.

spires no dread among the friends of constitutional liberty. In the war that followed the revolution of 1688, our navy consisted of about 30,000 seamen; that of Louis XIV. was not inferior until the battle of La Hogue in 1692. In the war of 1740, our force was carried to 40,000, and eventually to nearly 50,000 seamen. In the succeeding war, the vote in the year 1760 was for 70,000, a number till then unprecedented. Last war, when we had 140,000 seamen in service, and above 30,000 marines, there were in commission nearly 160 sail of the line, and 150 frigates. At present, the reduced state of the naval power of other countries has led to our peace establishment being brought so low as 13,000 seamen and 6000 marines. There are thus only five sail of the line in full equipment; the guard-ships have only a fifth of the war complement; and the other vessels in commission are chiefly employed in the prevention of smuggling. Still the annual vote for this department is large, in consequence of the great exertions made in peace for rebuilding our shipping and improving our dock-yards. In 1817, the navy estimates were,

19,000 seamen and marines; wages, victualling, &c.	L.1,672,000
Half-pay and pensions,	1,230,000
Building and repairs,	1,391,645
Ordinary of navy and repairs,	1,243,457
Provisions for ships abroad,	300,000
Transport service,	182,176
Sick and wounded,	79,350
	L.6,098,628

In 1818, the navy estimates amounted to L.6,457,000; in 1819, to L.6,436,000. The number of seamen receiving pensions without living at Greenwich hospital exceeds 30,000, of whom nearly the half are capable of active service.

List of Navy Officers on 30th September 1818.

Assistant-Surgeons,	367	161
Total,	8522	1081

Of the fortified places of England, the principal are the Dock-yards. Chatham contains an arsenal on a large scale; our dismantled vessels lie there in great numbers, and in the naval warehouses the stores are arranged in the highest order. Sheerness has of late years been greatly improved; a change which required all the resources of ingenuity and finance; the ground on which the town stands having been progressively formed by alluvial deposits from the Medway, and wanting, in a great measure, the consistency of primitive soil. Portsmouth has the largest victualling establishment after Deptford, and the greatest store of artillery after Woolwich; in point of edifices and works generally, it is our first naval station; it is also the usual port for the equipment of an armament. Plymouth possesses a road-stead of great depth and extent; and the anchorage has been lately much improved by the erection of the BREAKWATER, a great national work fully described in this *Supplement* under that head. Milford-haven is a still more capacious road-stead than Plymouth, and would form a most valuable depôt were its position less remote; as yet it has been used only for shipbuilding.

Revenue and Expenditure.

Various particulars relative to the government and economy of both army and navy will be found under the Articles ACADEMIES,—MILITARY; BARRACKS; DOCK-YARDS; GREENWICH HOSPITAL; NAVY.

XII.—*Revenue and Expenditure.*

The revenue of England, in the reign of Queen Elizabeth, hardly exceeded L.600,000 a-year; under Charles I. it was about L.800,000; under Charles II. from L.1,200,000 to L.1,500,000. James II. raised it to L.2,000,000, a sum, however, which fell considerably short of the contemporary revenue of Holland, and was not above a third of that of France. After the revolution, the necessity of great military efforts led to the imposition of the land-tax, and the average revenue under King William was about L.4,000,000; under Queen Anne, the same motives for exertion produced an augmentation to L.5,000,000, and eventually to L.6,000,000. In the pacific reign of George I. the revenue rather exceeded L.7,000,000, and a farther, but gradual augmentation took place towards the middle of the century.

Increase of the Public Revenue during the reign of George III.

These tabular statements form a history of our finances since 1803, and are so comprehensive as to render unnecessary any other observation, than that there is seldom an equality between the amount received and expended by government, because the accounts of the one year are necessarily blended with those of the succeeding. The deficiency of revenue in 1817 was met by a large issue of Exchequer bills. In 1818, the revenue improved by nearly L.2,000,000; but there still remained a deficiency of L.13,000,000, which necessitated a recourse in that year to temporary expedients; and, in the present year (1819), to a loan and a vote of large additional taxes.

National Debt. Our national debt originated in the great struggle made under King William, against the aggrandizement of France. It amounted,

At the peace of Ryswick, in 1697, to	L.21,516,000
At the peace of Utrecht, in 1714,	53,681,000
At the peace of Aix la Chapelle, in 1748,	78,293,000
At the peace of Paris, in 1763,	133,960,000
At the peace of Versailles, in 1783,	238,231,000

Sinking Fund. So early as 1716 a sinking Fund was commenced and persevered in with considerable firmness by Sir R. Walpole. The supplies for it were derived partly from surplus taxes, partly from a reduction of the interest of the existing debt. In 1733, an extraordinary demand for money caused a trespass on the inviolability of this fund, and the principle once infringed, there was no limit to subsequent encroachments. The sinking fund continued to bear the name, but it had not, so lately as 1772, discharged 15 millions of the public debt. At last, in 1786, Mr Pitt revived this measure, following in substance the plan of Sir R. Walpole, but investing the new reserve with additional precautions, by nominating a special Board of Commissioners, and rendering them independent not merely of the treasury, but, in some respects, of Parliament. It was then that the public first became familiar with the term *Consolidated Fund,* which means nothing more than the aggregate of the permanent taxes; from which aggregate government pledged itself to pay a million yearly to the commissioners for the redemption of the public debt. This fund of a million was to be farther augmented by public annuities as they expired, and by the interest of the redeemed debt, which was to be paid as formerly by government at the bank, but into the hands of the sinking fund commissioners. The measure, now brought into operation, paid off the following sums:

In 1787,	L. 662,750 stock.
1788,	1,456,900
In 1789,	L.1,506,350 stock.
1790,	1,558,850
1791,	1,587,500
1792,	1,507,100

The extinction of these sums, so inconsiderable at present in our eyes, had a powerful effect in reviving public confidence and raising the price of stock. The only dread was lest a renewal of war should necessitate new loans of far greater amount than these annual liquidations. To counteract this impression Mr Pitt added, in 1792, an annual L.200,000 to the previous million, and (what was of much more importance) obtained an act of Parliament, declaring that all future loans should carry in themselves the means of their gradual extinction, by including, for the sinking fund, a surplus of one *per cent.* over and above the money required for the current service. This provision, and the great commercial prosperity of the year 1792, produced a rise of the three *per cents.* to the extraordinary price of 98; but this flattering prospect was soon overcast by the wars of the French revolution. After these wars burst out, our financial operations assumed a very different aspect; for though our debt sustained a periodical reduction from the sinking fund, it was augmented in a much greater proportion by the new loans.

Table of the National Debt, and of the Operation of the Sinking Fund, the whole stated not in Money, but in Stock.

Years.	Total of Debt.	Paid off each Year by the Sinking Fund.	New Debt Contracted.	Debt remaining Unredeemed.
1793	L.238,231,248	L.1,962,650	L.————	L.227,989,148

1816	1,003,090,282	20,647,122	70,888,402	699,315,516
1817	1,006,090,282	19,546,201	3,000,000	682,769,314
1818	1,109,123,032	18,512,227	————	748,201,991

The great addition in the last year arises from the consolidation of the British and Irish Exchequers, by which above L.100,000,000 of stock were added to the mass, without, however, producing any virtual change in our finances; the interest of by far the greater part of the Irish debt having been previously paid in England. As the larger proportion of our debt bears only three *per cent.* interest, and is, of

National Income and Capital.

course, considerably below the value of L.100 money for L.100 stock, the value in cash of our debt would not (taking the three *per cents.* at L.75) exceed L.700,000,000, were there not a large addition to be made from Long Annuities and unfunded debt; the effect of which is to carry the value of the whole public debt in cash to nearly L.750,000,000. But as there seems no more reason to anticipate the liquidation of the debt of England than of that of other countries, the more correct plan is to follow the French method of computing a financial burden by the amount of the annual interest. This, in our case, is above L.46,000,000, if we include our annual payments to the sinking fund; or somewhat more than L.31,000,000, if we leave that fund out of the question.

XIV.—*National Income and Capital.*

An inquiry into this subject, interesting to every civilized nation, is of vital importance to one so loaded with taxation as England, and still doubtful of the time when she may recover from the unparalleled burdens of the late contest. Mr Pitt, on first proposing the income-tax in 1798, made the following estimate of the annual income of England and Scotland:

England—Rent of land, after deducting one-fifth, . .	L.20,000,000
The tenants' income, deducting two-thirds of the rack-rent, .	6,000,000
Tithes, deducting one-fifth, .	4,000,000
Mines, iron-works, canals, timber, tolls, &c. deducting one-fifth, .	3,000,000
Rent of houses, deducting one-fifth,	5,000,000
Profits of professions, . .	2,000,000
The same for **Scotland**, taking it at one-eighth of England, . .	5,000,000
Income of persons residing in Great Britain, derived from our colonies,	5,000,000
Dividends from the public stocks, deducting one-fifth for exemptions and modifications, . .	12,000,000
Profits of trade, foreign trade, .	12,000,000
——— home trade and manufactures,	28,000,000
	L.102,000,000

This estimate was examined with great attention by the Reverend Dr Beeke,* who pointed out several heads, in particular tithes, which the minister had overrated; while in others, such as the rent of houses, his computation was below the mark. Since that period, the income of our countrymen, at least the income as represented in money, has experienced a considerable rise, and the returns under the *property-tax* have afforded a variety of useful *data.* We select the year 1810, as the latest return before the depreciation of our bank paper, and as equal (we fear more than equal) to the amount that would be declared in time of peace.

National Income and Capital.

Rental of lands, . .	L.29,500,000
Tithes, . . .	2,360,000
Rental of houses, . .	13,000,000
Mines, quarries, and iron-works, .	740,000
Trade and professions, . .	32,200,000
Interest of money in the public funds, or on mortgage; salaries from public offices, and all sources not already specified, . . .	47,700,000
	L.125,000,000

Such are the returns under the property-tax; but to this we must add a considerable sum for the deductions allowed by government on incomes between L.50 and L.200 a-year, and a much greater for the wages of the lower orders. Of the population of England and Scotland, a vast proportion were wholly exempted from the property-tax, their incomes being below L.50 a-year. Supposing that the property-tax since the peace, would render somewhat less than in 1810, but that with the addition of the deductions for small incomes (from L.50 to L.200) the total return would be L.130,000,000, and adding to this L.70,000,000 for those wholly exempted, we have for England and Scotland an amount of L.200,000,000; to which, adding for Ireland (which has never been subjected to property-tax), a conjectural amount of L.25,000,000, the aggregate of the national income would be L.225,000,000. This sum is considerably below the estimate of a writer of the present day (Mr S. Gray *on the Happiness of States*); but he makes no allowance for the depreciation consequent on the change from war to peace; and does not, moreover, distinguish between that which is income, and that which is properly created, or the annual produce of land and labour. This distinction will be best understood by transcribing from Dr Colquhoun's late work on the British empire, his

Estimate of Property created in Great Britain and Ireland in the year 1812.

Agriculture in all its branches,	L.216,817,624
Mines and minerals, including coals,	9,000,000
Manufactures in every branch, .	114,230,000
Inland trade in all its branches, .	31,500,000
Foreign commerce and shipping, .	46,373,748
Coasting trade, ...	2,000,000
Fisheries, exclusive of the colonial fisheries of Newfoundland, . .	2,100,000
Chartered and private bankers, .	3,500,000
Foreign income remitted, . .	5,000,000
Total,	L.430,521,372

A farmer's income is the profit resulting from his capital and labour; but the corn raised, or, in other words, the "property created" by him in the course of a year is obviously four or five times that amount. A manufacturer, in like manner, makes goods to an extent of probably ten times his income; so that the two estimates,—we mean that of income and that of property created, accord only in the case of professions, of salaries, of wages; and the result is, that the total property created in a year is nearly double that of income,—a distinction which explains the misapprehension of M. Say and others who have taxed Dr Colquhoun with exaggeration.

---

* *Observations on the Produce of the Income Tax, and on its Proportion to the whole Income of Great Britain.* 1800.—Pamph.

What proportion does our taxation bear to our national means? Taking our taxes as fixed by the late acts (July 1819), and estimating them by their gross produce,—such being the payment by the people, and adding the amount of poor-rates, we have (without considering the corn-laws in the light of a tax, and leaving the sinking fund altogether out of the question) an annual burden of fully L.70,000,000 Sterling, or one-third of the national income of Britain and Ireland!—while France, whose national income is at least equal to that of the three kingdoms, is subjected to a taxation of only half the amount.

The next topic in this inquiry regards the amount of national capital. We subjoin two calculations, both inclusive of Scotland, and both made in the early part of this century.

Mr Grellier's Computation.

Value of land in England and Scotland, . .	L.828,660,000
Houses, ...	199,575,000
Cattle, and all kinds of farming stock, . .	102,500,000
	L.1,130,735,000

Dr Beeke's.

Value of land in England,	L.600,000,000	
——— in Scotland,	120,000,000	
Value of tithes in England,	75,000,000	
		L.795,000,000
Houses, . . .		200,000,000
Farming capital, . .		125,000,000
Mines, Canals, Timber, Tolls, &c.		100,000,000
		L.1,220,000,000

Mr Grellier went very little farther, but Dr Beeke makes several very important additions, viz.

Value (in 1800) of the public funds, ...	L.300,000,000
Value of our trade; home trade, ...	120,000,000
——— foreign trade and shipping, ...	80,000,000
Unproductive property; viz. furniture, plate, lands not yet cultivated, . .	280,000,000
Total of England and Scotland,	L.2,000,000,000

To this Dr Colquhoun adds a conjectural estimate for Ireland; and, writing in 1814, computes the whole as follows:

	Productive Property.	Unproductive.	Government Property.	Total of each Country.
England and Wales, ...	L.1,543,400,000	271,500,000	32,000,000	1,846,900,000
Scotland, ...	239,580,000	38,500,000	3,000,000	281,080,000
Ireland, ...	467,660,000	87,000,000	9,000,000	563,660,000
Military stores and other property common to Britain and Ireland, . . .				45,000,000
Total of each kind of property,	L.2,250,640,000	397,000,000	44,000,000	2,736,640,000

XV.—*Population.*

The population of England and Wales may be computed with considerable accuracy, so far back as 1377, from the returns of a poll-tax imposed that year; when the total of all ages and sexes appears to have been about 2,300,000. The succeeding century, passed in a great measure in civil war, could not be a period of large increase; but these contests were happily closed by the accession of Henry VII. in 1485, and followed, in the reign of his son, by the adoption of a religion more favourable to productive industry than the Catholic creed, with its endless holidays. These advantages, and the wise government of Elizabeth, rendered probable the great increase to be inferred from the survey made in 1575 (the season of dreaded invasion from Spain), the result of which seems to give an aggregate of 4,500,000. In the succeeding century, the chief *data* of computation are the official records of houses in the Hearth Office; from which it seems probable that the population of England and Wales, at the time of the Revolution, was between five and six millions. At last, in 1801, and again in 1811, clear and accurate returns were obtained, under acts of Parliament, when the total population of England and Wales was found to be,

In 1801,	9,343,578
In 1811,	10,791,115

The increase, in ten years only, was 1,447,537, or at the rate of 14½ *per cent.* for England, and 13 *per cent.* for Wales.

Return of 1811.

Inhabited houses, . .	1,797,494
Number of families, . .	2,142,147

Population.

Families employed in agriculture,	723,397
——— in trade, manufactures, and mechanical labour,	959,622
Towns, great and small,	939
Town population,	4,365,281
Country population,	5,785,334
Male inhabitants,	4,867,396
Army and Navy,	640,500
Total males,	5,507,896
Females,	5,283,219
Total population,	10,791,115

Inhabitants per Square Mile.

England, not 186, as has been stated, but	198
Ireland,	122
Wales,	80
Scotland,	56

Marriages, on an Average of Ten Years, from the Official Returns.

1755 to 1765,	56,275
1765 to 1775,	59,892
1775 to 1785,	65,479
1785 to 1795,	71,784
1795 to 1805,	79,231
1805 to 1810, (average of five years),	82,953

This increase of marriage is altogether a consequence of a previous increase of population; for it appears that the proportion of marriages among an equal number of persons has not augmented; the returns showing,

From 1780 to 1790, 1 marriage among 117 persons.
—— 1790 to 1800, 1 among 119½
—— 1800 to 1810, 1 among 119½

The average of deaths varies considerably, being much greater in towns than in the country. In Middlesex, there are 1 annually for 36 inhabitants; in Surrey, 1 in 45; in Lancashire, 1 in 48; while, in the healthy agricultural districts, they do not exceed 1 in 60; and, in Wales, rise still higher, being only 1 in 64 or 67. Still the ratio of increase in population is much larger in towns, owing apparently to two causes—the greater frequency of marriages, and the incessant removal of persons from country to town.

Population of the Principal Towns of England.

	Year 1801.	Year 1811.
London,	900,000	1,050,000
Manchester,	81,020	98,573
Liverpool,	77,653	94,376
Birmingham,	73,670	85,753
Bristol,	63,645	76,433
Leeds,	53,162	62,534
Plymouth,	43,194	56,060
Portsmouth,	32,166	40,567
Norwich,	36,832	37,256
Sheffield,	31,314	35,340
Nottingham,	28,861	34,253
Bath,	32,260	31,496
Newcastle-upon-Tyne,	28,365	27,587
Hull,	29,516	26,792
Bolton,	17,416	24,149
Leicester,	16,953	23,146

For an account of the Laws of England, and of the administration of Justice, we must refer to the articles Law and Court in the *Encyclopædia;* and to the articles King, Lords, Commons, and Parliament, for an account of the form of Government, and of the powers and functions of the different branches of the Legislature. (D.D.)

ENTOMOLOGY.

Entomology (from ἔντομον an insect, and λογος a discourse) is the name of a science, embracing the study of all such annulose animals as have articulated legs; namely of *Cirripides, Crustacea, Myriapoda, Acari, Arachnoïda,* and *Insecta.*

Under the head Annulosa (Vol. I. p. 401—429—432 and 447) we have already given a rapid sketch of the principal systems that have been proposed by various authors. In the present article it is our intention to exhibit an historical view of the rise and progress of Entomology, and to enumerate, with general remarks, all the works and dissertations that have come under our view.

Of the most ancient writers on this subject we are totally ignorant; we know only that insects were not unnoticed by Moses, who frequently alludes to them in the sacred writings; and it is said that Solomon cultivated this as well as other branches of natural history.

Linus, a poet of Thebes, is the first author who is recorded to have described all animals and plants. After him, Orpheus, Anaxagoras, Archelaus, Democritus, and Hippocrates, are quoted by Pliny and other authors, as having studied Insects; but we believe that none of their works on this subject are now extant.

Aristotle wrote on insects. In the seventh chapter of his first book, we find his ἔντομα accurately distinguished from the other animals of the group of exsanguineous animals, with which he arranged them. In the first chapter of the fourth book, the essential external characters are more clearly given: namely, the incisions on the back and belly, &c. In another part of his work, he describes them as being composed of three parts, the head, trunk, and abdomen; and mentions their legs. In subsequent passages, he describes insects that fly, and those that walk. Amongst the former, he notices those with naked and those with sheathed wings; he observes, too, that some have these sheaths divided, and others immoveably connected; he distinguishes also insects with two and insects with four wings; and observes, that the latter are often furnished with stings, whilst the former are always destitute of these weapons. The modifications in the form of the antennæ and legs of insects, he has likewise described with accuracy. A cursory perusal of this work will astonish the modern Entomologist, who will be surprised at its consistency, and with the accordance of the author's divisions with the present systems of Entomology. Alexander the Great furnished Aristotle with means of cultivating science, which no other philosopher ever enjoyed; yet, notwithstanding these advantages, and his astonishing powers of mind, his writings contain too great an accumulation of knowledge, to have been the result of his individual inquiries: and we are perfectly convinced, from the slow manner in which all human knowledge is developed, that the study of nature must have made very considerable advances before his time; and that he must have derived assistance, either from his pupils, or from the labours of more ancient naturalists.

Speusippus and Leonides, pupils of Plato and Aristotle, are quoted by Atheneus, as having turned their attention towards Insects.

Xenocrates, who lived in the 110th Olympiad, in his six books on Nature, treated of Insects.

Theophrastus, too, an auditor of Plato and Aristotle, notices Insects in his writings.

Antigonus, who flourished under Ptolemy II. in a work, which was published at Leipzic in 1791, alludes to the manners of Insects.

Amongst the Greek writers who immediately, or within a few centuries, followed Aristotle, treating on Insects, we find quoted the names of Democritus, Neoptolemus, Philistus, Nicander, and Herodius. These writers are supposed to have been contemporary with Pliny; and, during the same period, several Latin writers seem to have pursued the science through the influence of the Greeks, who were insensibly led to it, from their culture of bees, which was at that time attended to with the most enthusiastic ardour. Aristomachus is said to have written on the subject, from the result of fifty years' experience; and Philiscus to have employed his whole life in deserts and forests attending to their history.

Publius Nigidius Figulus, who flourished about sixty-four years before the birth of Christ, wrote a work on animals, in which insects are sometimes mentioned.

M. T. Varro, contemporary with Cicero, in his work, " De re Rustica," is the first Roman author who mentioned Roman insects, and Cicero, himself, has not unfrequently noticed insects in his " De Natura Deorum."

P. O. Naso, born in the first year of our era, is quoted as an Entomologist.

L. J. M. Columella lived under the Emperor Claudius, and, in his work, " De re Rustica," takes notice of various insects.

Pliny, the most celebrated of all the Roman naturalists, in the eleventh book of his Historia Naturalis treats of Insects. His observations on this subject are chiefly copied from Aristotle, and he has made use of the observations of various other writers, whose works he quotes; and has sometimes described species with tolerable exactness. Insects, indeed, seem to have occupied a considerable portion of his attention, and to have been a favourite study. " *In his,*" says he, " *tam parvis tamque fere nullis quæ ratio! quanta vis! quam inextracabilis perfectio!*" In his day, the culture of silk-worms was an object of peculiar attention: He says that garments of silk were very much admired by the fair part of the community, as they showed their form to great advantage. Pliny has frequently described the economy of animals with very great accuracy, but he has often admitted, on the authority of others, the most absurd and improbable fables.

Claudius Ælianus, a Roman who flourished under Adrian in 120, wrote twenty-seven books on animals, entitled Περὶ ζῶων, and has appropriated several chapters to Insects, describing the generation of wasps, &c. often accompanied with fiction.

From the time of Ælian until the overthrow of the Roman Empire, the study seems not to have been totally disregarded; but we are ignorant what progress was made during that period; between which and the middle ages, we find the names of Titus, Ætius, Alexander, Oribasius, Trallian, Paulus Ægineta, Lucius Apuleius, Athanæus, Oppianus, Marcus Aurelius Olympius, St. Ambrosius, Epiphanus Cyprius, Decius Magnus Ausonius, Æmilius Marcus, Merboldus, and Cassiodorus Isodorus, whose works contain general remarks on Insects, more or less mixed up with fiction.

Between the ninth and twelfth century, some of the Arabian botanists distinguished themselves as Entomologists. The principal were Rhazes, Avicenna, Avenzoar, and Averrhoës. From this period until the fifteenth century, a few obscure writers, scarcely worthy of notice, appeared; viz. Myrepsus, Platerus, and Lianus.

About the twelfth century, Hildegardis de Pingua wrote four books, entitled " Physica St. Hildegardis," published in 1533 and 1544 in folio.

In the thirteenth century flourished Albertus Magnus, who wrote a work, entitled " De Naturis Animalium," part of which treats of Insects, in an obscure and barbarous manner. His works, in twenty-one volumes folio, were published at Lyons in 1657.

In the same century lived the celebrated Vincentius Bellouacensis, a French philosopher, who likewise cultivated the study of Insects.

Some time in the fourteenth century, an obscure work, entitled " Jorath De Animalibus," was written, and in the same era also, another work, " De Natura Rerum," both of which mention insects.

About the middle of the fifteenth century, Theodorus Gaza translated the works of Aristotle on animals into Latin. Towards the end of the same century, Hermolæus wrote " Castigationes Caii Plinii." Romæ, 1492 et 1493, Basil, 1589; of which there were also several other editions. Jonannes Cuba, author of a work entitled " Hortus Sanitatis," &c. Argent, 1536, is supposed to have lived in the same era.

Agricola, in 1549, published a systematic arrangement of Insects in his work " De Animalibus Subterraneis," in which he reduces all insects to three principal classes, viz. 1. Those that walk. 2. Those that fly. 3. Those that swim; and describes a number of species.

In the beginning of the sixteenth century, Gregorius wrote his excellent work in German, on Birds and Fishes, of which there is a Latin edition. Insects are mentioned in this work.

In this year appeared a work by Paulus Jovius, " De Piscibus Romanis," Basil, 1531; of which a second edition was published at Rome in 1524.

Petrus Gyllius, a Frenchman, published " De Natura Animalium," Lugd. 1533.

In this year the celebrated Conradus Gesner published his " Historia Naturalis;" A work to be consulted by the Entomologist. Gesner was born in 1516, and died in 1558.

In 1552, Edward Wotton published his work " De differentiis Animalium," Paris, 1552, in which he treats largely on Insects. The book is in folio, and appeared three years before the author's death.

Rondeletius this year produced his little work, " De Piscibus Marinis, cum universa Aquatilium historia, et de Insectis et Zoophytis." Lugd. Gall. 1554; and, in the following year, published his " Universa Aquatilium historia pars altera." Ludg. Gall. 1555, fol. The third book of which treats of Insects, and is accompanied by rude wood cuts.

Petrus Andreas Matthiolus in this year published his " Commentarii de Medica Materia," &c. Venet. 1583, which is illustrated with figures.

A little work by Gesner, entitled " Serpentiam Historia et Insectorum Libellus," was published in this year.

In this year appeared " Ferrante Imperato dell' Historia Naturale." Naples, 1599. And " Xenocrites De Natura, Libri sex. Cura Gesneri." Turici, 1559.

Ulysses Aldrovandus published a very voluminous work, " De Animalibus Insectis," Bononiæ, 1602. fol. This indefatigable compiler has certainly acquitted himself very well in collecting together the undigested observations of the ancients, considering how entirely he was ignorant of the subject himself. He has consequently fallen into all the errors of his predecessors; but has very rarely omitted to mention his authorities. He was professor of medicine at Bologna, and spent much of his time and money in acquiring insects, and in employing artists to figure them. He is stated to have paid two hundred florins annually to an artist, who was solely occupied in the delineation of Insects. Aldrovandus divides insects into two great groups, 1. Terrestrial: 2. Aquatic, which he terms Insecta farica, and non farica; these he again distributes into minor groups from the number and situation of their wings and feet. His figures are but rudely executed; but as the art of engraving on copper had at that period but scarcely emerged from its infancy, such works were almost exclusively produced by artists themselves.

Wolfang Franzius published, in 1612, his " Historia Animalium Sacra," in which insects are divided into, 1. Aëria; 2. Aquatica; 3. Terrea; and are described with greater accuracy than in any former work.

A pamphlet of about an hundred pages, entitled " Jeremiah Wilde De Formica," appeared in Rome.

In 1622, a work but remotely relating to Insects was published in Edinburgh, bearing the following title, " Hieroglyphica Animalium Terrestrium, &c. quæ in Scripturis Sacris inveniuntur et plurium aliorum, cum eorum interpretationibus." 4to.

A thin quarto, containing 226 miscellaneous figures of insects, was published under the title of " Diversæ Insectorum volitantium Icones ad vivum depictæ, per D. J. Hoefnagle, typisque mandate a N. J. Vischer."

The work of Thomas Mouffet, entitled " Insectorum sive minimorum Animalium Theatrum." Londini, 1634. fol. This is the first work on Entomology published in Britain; it is ornamented with several wooden cuts, rudely executed, accompanied by long, tedious, and often fanciful descriptions of the species. The first seven chapters are occupied with heavy details concerning the common hive bee (Apis mellifica). The eighth is entitled, " De Vespis:" the ninth, " De Crabrone et Tenthredine," which includes descriptions of the humble-bees (Bombi). The three following chapters, " De Muscis," under which are comprehended several Dipterous, Hymenopterous, and Neuropterous insects. The thirteenth, " De Culicibus." The fourteenth, " De Papilionibus," which occupies two hundred pages, the margins of which are embellished with one hundred and twelve wooden figures, executed in the rudest style; yet in most instances they are tolerably intelligible. The fifteenth, " De Cicindela," including the glow-worm (Lampyuris) and several other genera. The seventeenth, " De Locustis." The eighteenth, " De Blattis." The nineteenth, " De Buprestide et Cerambyce." The twentieth, " De Cantharide." The twenty-first, " De Scarabæis," including several of the larger Coleoptera. The twenty-second, " De Scarabæis minoribus." The twenty-third, " De Proscarabæo et Scarabæo aquatico." The twenty-fourth, " De Gryllo-talpa." The twenty-fifth, " De Phryganea." The twenty-sixth, " De Tipula." The twenty-seventh, " De Forficula sive Auricularia." The twenty-eighth, " De Scorpioni, Formica, et Pediculis alatis;" and lastly, the twenty-ninth, " De Cimice Sylvestri." We then arrive at the second book, which treats of apterous insects, amongst which he arranges all sorts of larvæ or caterpillars, and several vermes. We must apologise to the reader for having taken up so much of his time with the above dry extracts; but as they occur in the earliest of our works, we trust they will not prove entirely uninteresting. We shall conclude with quoting the following passage, relating to a species of *mantis*, as a specimen of his style and notions relative to the subject: " Pectus habet longum, tenue, cuculo tectum, caput simplicem; oculos sanguineos, satis magnos; antennas breves; pedes sex locustarum more, sed anteriores multo crassiores longioresque cæteris, quos quia junctos plerumque elevat (præcantium ritu a nostratibus *presque Dieu* dici solet;

totum corpus macilentum est. Tam divina censetur bestiola, ut puero interroganti de via, altero pede extenso rectam monstrat, atque raro vel nunquam fallat. Cauda illi bifurca, setaceis duobus aculeis prædita; atque ut manuum elevatione vates refert, ita etiam et motus similitudine; neque enim ludit ut alii, neque saltat, neque gestit; sed lente obambulans modestiam retinet et maturam quadam ostendit gravitatem." This work is professedly an improvement on that of Dr Wotton, begun in 1550, continued by Gesner, and afterwards published in its present form by Mouffet.

In 1646, Hollar gained considerable reputation by his work, "Muscarum, Scarabæorum, Vermiumque variæ Figuræ et Formæ, omnes ad vivum coloribus depictæ," &c. Antwerp.

In this year, Johnson published his "Historia Naturalis" in folio; but, as this work is a mere compilation, without a single new remark, it is unworthy of farther notice.

An English translation of Mouffet's work was published in London by Topsal.

Dr Mey, minister of Middleburgh, published a Latin translation of Goedart's work, entitled, "Metamorphoses et Historia Naturalis Insectorum, 1662."

In 1664, a quarto relating to insects as objects of microscopical observations by Power, was published.

In 1665, "Hook's Micrographia" appeared, treating of minute insects.

C. Merret, in 1667, published in London his celebrated "Pinax rerum naturalium Britannicarum, continens Vegetabilia, Animalia et Fossilia, in hac Insula reperta inchoatus." As this is the earliest book treating exclusively of British insects, it is not devoid of interest. It contains a brief catalogue of such species as were known to Dr Merret, with a concise descriptive sentence, by way of name. In the first volume of the "Transactions of the Entomological Society of London," an account of the insects enumerated, with their systematic names, is given by Haworth.

Charlton produced his "Onomosticon Zoicon," London, 1668, 4to, which contains a systematic arrangement of insects after the manner of Aldrovandus.

In 1669 was printed in Dutch, with a Latin title, at Utrecht, "Historia Insectorum Generalis," &c. by the celebrated Swammerdam. This work was printed in quarto, illustrated with thirteen copperplates. Many years elapsed before this great work, the admiration of later times, was in any manner acknowledged. It was condemned as inaccurate until the death of its learned author; but no sooner was his death announced, than his value was discovered, and his work was translated into the French language. This was shortly after followed with other editions. Swammerdam divided insects into four groups, the characters being taken from their metamorphosis and economy. The first undergo no change, such as *spiders*, *onisci*, &c. (The classes *Crustacea*, *Myriapoda*, *Arachnoïda*, and *Acari*, of the moderns.) The second includes those which, after leaving the egg, appear under the form of the perfect insect, but have no wings, in which state they eat and grow, till, having shed their skin, they appear in the winged form, and are capable of propagating their kind. (The orders *Orthoptera*, *Dermaptera*, *Dictuoptera*, *Hemiptera*, and some of the *Neuroptera*.) In the second group are comprehended those insects which appear, when hatched from the egg, under the form of a caterpillar, which, when full grown, changes into a chrysalis, where it remains until the parts are fully developed. The insects included under this head are, the orders *Coleoptera* and *Aptera*. The fourth group comprehends those who, having attained their pupa state, do not divest themselves of their skin, namely, the *Hymenoptera* and *Diptera*.

Wolf's "Dissertatio de Insectis," &c. was published at Leipsic, during the same year. The author was Professor of Medicine at Jena.

In 1661 was published, in 12mo, "Redi Experimenta circa generationem Insectorum," in which the long maintained and ridiculous doctrine of equivocal generation is most successfully overthrown.

Claude Perault, one of the most learned exotic Entomologists of his age, author of several very valuable papers in the "Memoirs of the French Academy," published a folio work in Paris, entitled, "Memoires pour servir à l'Histoire Naturelle des Animaux," 1671.

In 1672, Ferrard published a work on Insects, at Naples, We have never met with it, but it is highly spoken of.

Franzelio, in 1673, submitted his "Insecta Novisolii cum nive delapsa" to the world.

In the same year, Mollerus published at Franckfort, "Meditatio de Insectis quibusdam Hungaricis prodigiosis anno proxime præterito, ex aëre una cum nive in agros delapsis," ornamented with wooden cuts.

Swammerdam published, in 1675, a tract on the natural history of the *Ephemera horaria*, entitled, "Ephemeri Vita."

In the same year, an elementary tract was printed at Upsal, by G. Belerio, named, "*περὶ τῶν ἐντόμων*."

And about the same time, by Samuel Bochart, a work, entitled, "Hierozoicon, sive bipartium opus de Animalibus Sanctæ Scripturæ."

In 1676, some additions to Claude Perault's work were published.

In 1691, Madame Maria Sybilla Merian, or Gräffinn, produced the first part of her work, "Der Raupen wunderbare verwandelung und sonderbare blumen-nahrang," which relates principally to European insects, of the order Lepidoptera. The authoress was a native of Frankfort on the Maine, wife of John Andrew Gräffinn. In early life she imbibed a taste for the study of insects, from being occupied at times in painting these objects as ornaments to her flower-pieces, in which she is said to have excelled. The task of painting insects she performed with tolerable accuracy; yet there is a wireiness in the outline, and "a peculiar exuberance of style, incompatible with any faithful resemblance of nature." Many of her original drawings are preserved in the British Museum, as specimens of her performance.

In 1680 was published, "Johannis Jacobi Wagneri, Historia Naturalis Helvetiæ curiosa," with figures.

Grew, in 1681, published his "Museum Regalis

Societatis," being a catalogue, with descriptions of the natural and artificial curiosities, belonging to the Royal Society of London, preserved in Gresham College. London, folio.

In the same year, an English translation of Swammerdam's "Ephemeri Vita" was published in London, and a French translation in Paris.

In 1682, a book, entitled, "Johannes Godartus of Insects, done into English, and methodised, with the addition of Notes; the figures etched in copper, by Mr P. Fib;" was published at York. It is supposed to have been translated by Martin Lister; the initials M. L. being at the close of the address to the reader. The impression, as we learn from the preface, consisted of one hundred and fifty copies, which were intended merely for the curious. The notes are copious.

Hoppis, in the same year, published a Dissertation on the Migratory Locust.

In 1683, the second part of Merian's "Der Raupen," &c. appeared.

In 1685, the first Latin edition of Swammerdam's great work was printed in Lyons, under the title, "Historia generalis Insectorum, Latinam fecit H. C. Hennius."

In this year also, Lister's Latin edition of Goedart, entitled, "J. Goedartius de Insectis in methodum redactus, &c. Opera, M. Lister, &c. Item Appendices ad Historiam Animalium Angliæ, Ejusdem M. Lister, Londini, 1685," 8vo. Illustrated with several copperplates. In this work Lister has distributed the materials of the work into a new form of arrangement, the merits of which are too obvious, not to be considered as an important improvement on the original production. He divides them into ten sections, as follow:

1. Those with erect wings and angulated pupæ, *Butterflies*.
2. Those with horizontal wings, proceeding from caterpillars, called by Goedart, *Geometræ*.
3. Those with deflexed wings, *Moths*.
4. Libellulæ, or dragon-flies.
5. Bees.
6. Beetles.
7. Grasshoppers.
8. Flies with two wings.
9. Onisci or Millipieds.
10. Spiders.

Although we allow to Lister all the credit due for this arrangement, yet we cannot avoid expressing our regret at his remarks on the original author, to whom he allows neither credit as a naturalist nor as a writer. He highly praises his skill as a painter; but says, "Goedart, after forty years' attention, seems to have made but little advancement in his skill in the nature of insects; he rather appears to have diverted himself, than to have given himself any trouble to understand them; and yet, after all, you will find him every where just and correct, but in many places short and hardly intelligible." These opinions are delivered in a style of highly unbecoming affected superiority over his author, and have gained him no reputation on the Continent, where he has been much neglected and condemned for his illiberality.

In 1687, Leuwenhoek produced his "Anatomia seu interiora rerum, cum animitarum tum inanimitarum, ope et beneficio exquisitissimorum microscorum detecta."

Geyereus, in the same year, wrote a treatise on the medical effects of Spanish flies (Cantharides), entitled, "Tractatus Physico-medicus de Cantharidibus."

J. F. Griendel, about the same period, published at Neuremberg, in quarto, "Micrographia Nova," in which some notice is taken of insects.

In 1688 was published an Italian edition of Redi's experiments, entitled, "Esperienze intorno alla Generazione degl' Insetti."

In this year also, Stephen Blankaart of Amsterdam published a work, "Schon Berg der Rupsen, Wormen, Maden en vliegende Dierkens daar uit voort-kommende." The author was a physician, who devoted much of his time to collecting insects. The plates are admirably executed; but the work in other respects bears but a very indifferent character. It treats of the larvæ of various insects, and a few in the perfect state are also noticed. Frisch and Lyonet consider it but a superficial production. Another edition was published at Leipsic in 1690.

John Cyprien also published at Frankfort, "Historia Animalium," in the same year, in which insects are noticed.

About this period, two papers on insects are mentioned as having been published, one by John de Muralto, the other by C. Mentzelius.

In 169[illegible], Bilberg published, at Upsal, a dissertation, entitled, "Locustæ."

Also König's "Regnum Animale."

And Stephanus Blancard published, in 8vo, at Leipsic, his "Schon-burg der Ruspen, Wormen, Maden."

In 1691, the "Historia Vermium," by Jungius, was printed at Hamburgh.

In 1692, in the "Memoirs of the French Academy," we find a curious paper, by Sedileau, entitled, "Observations sur l'Origine d'une espéce de Papillon," which treats of *Saturnia Pavonia-major*.

In 1693, an augmented edition of Swammerdam's work was printed at Utrecht, entitled, "Historia Generalis Insectorum, Latinam fecit H. C. Hennius."

In this year, the prodigious ravages occasioned by immense swarms of locusts, which, in the month of August, over-ran Germany, and extended partially through the rest of Europe, even to the northern borders, could not fail to engage the notice of many writers, amongst whom we find the following accounts. "Heberstreit; de Locustis immenso agmine aerem nostrum implentibus, et quid portendere putentur." This treatise is comprised in sixty-five pages, with one plate, from which we learn the species treated of to be *Locusta migratoria*. "Lodolphi Dissertatio de Locustis, anno præterito immensa copia in Germania visis, cum diatriba, qua sententia autoris de שלוים defenditur." In folio, consisting of eighty-eight pages, embellished with figures. The following authors also published tracts on this subject, namely Crelluis, Kirkmajor, Wollenhaupt, and Treunera; but we are ignorant of the titles of their little dissertations.

In 1694, Albino published a small tract on the Spanish flies (Cantharides).

In 1695 appeared the "Arcana Naturæ Detectæ," by Leuwenhoek.

And, in the same year, a small octavo, "Jacobi Petiveri Museum."

In 1699, Hombergh published a paper in the Memoirs of the French Academy, on *Agrion Virgo*, Fabr.

In 1700 was published, in 3 vols. duodecimo, "Histoire Naturelle des Insectes selon leurs différentes metamorphoses, observées par Jean Goedart. Amsterdam."

James Petiver, in 1702, produced the first decade of his "Gazophylacium Naturæ et Artis," which was carried on progressively during ten years. It consists of ten parts, which treat of insects, as well as of various animals, fossils and plants.

In 1705, our celebrated countryman Ray published his work entitled "Methodus Insectorum, seu in methodum aliqualem digesta."

In this year, also, the entomological part of the work of Rumphius appeared.

In 1707 appeared in London "A Voyage to the Islands of Madeira, Barbadoes, Jamaica, with the Natural History," &c. by Sir Hans Sloane, folio.

In 1710 Russel published his "Theatrum universale omnium Animalium," which treats of insects.

And in this year appeared Ray's posthumous work, "Historia Insectorum," which was brought out under the care of Dr Derham. Insects are defined to be animals, having their bodies divided more or less by incisions. The first division, *ἀμεταμορφωτα*, undergo no change, and consists of, 1. Ἀποδα or those without legs, under which he comprehended the class Vermes (Anneleides *Cuvier*), and some intestinal worms (*Entozoa*); 2. Pedata, including the classes Arachnoida, Myriapoda, Insecta Ametabolia, and some of the Crustacea Malacostraca Edriophthalma. The second division, *μεταμορφωτα*, pass through the state of larva, and contains all the Insecta Metabolia.

In 1717, Wedelio published a tract of the utility of Cantharides, in the Materia Medica of Jena.

In the same year, J. Petiver published a work in London, "Papilionum Britannicæ Icones, Nomina," &c. folio. This was certainly, in its day, a valuable acquisition to the student, and is still, as a work of reference, of some repute.

Frisch, in 1720, published his "Beschreibung von Insecten in Deutschland." The whole work consists of thirteen parts, illustrated, each, with plates.

Eleazer Albin published, in London, "A Natural History of English Insects," with one hundred copperplates, in one quarto volume.

In 1721, Bradley published in London, "A Philosophical Account of the Works of Nature," which contains some entomological matter, and a few engravings of insects, 8vo.

In 1722, Opera Omnia Leuenhoekii.

Sir Hans Sloane published in London, in 1725, the second volume of his "Natural History of Jamaica," the second book of which treats of the insects of that island, and is accompanied by several plates.

In 1726, Madam Mérian published at the Hague, in large folio, "De Generatione et Metamorphosibus Insectorum Surinamensium," the materials of which were collected by herself, or under her immediate direction, in Surinam, where she spent two years, for the sole purpose of forming a collection, and in taking drawings for this work; which is not, however, entirely devoted to Entomology, for, besides insects, we find plants, and various reptiles, as toads, lizards, serpents, &c. depicted.

In 1730, Valisnieri, in his "Esperienze et Observationi intorno agli Insetti," distributes all insects into four groups, from the following characters: 1*st*, Those living on plants: 2*dly*, Those living in water: 3*dly*, Those living on the earth, or amongst stones: 4*thly*, Those which subsist on other animals.

Eleazre Albin, in 1731, published, in a quarto volume, "Insectorum Angliæ Historia Naturalis illustrata Iconibus in centum tabulis æneis eleganter ad vivum expressis," &c. which came out in London, and was esteemed an elegant work. It is more remarkable for gaudiness than fidelity.

And, in the same year, in London, "Histoire Naturelle de la Caroline, la Floride," &c. par Marc Catesby, folio.

Reaumur published, in 1734, the first volume of his valuable "Memoires pour servir à l'Histoire des Insectes," in Paris. The five succeeding volumes appeared between that time and 1742.

In the same year, the first volume of the celebrated "Alberti Sebæ, Locupletissimi rerum Naturalium Thesauri accurata descriptio, et Iconibus Artificiosissimis, Expressio Latiné et Gallicé," folio. The three succeeding volumes appeared before 1765.

In 1735, the celebrated Swedish naturalist, Linnæus published the first edition of his "Systema Naturæ, sive Regna tria Naturæ systematice proposita per Classes, Ordines, Genera et Species," in which work he distributes insects into four orders, according to the number and form of their wings, under the names, 1. COLEOPTERA, or insects with covered wings. 2. ANGIOPTERA, those with naked or uncovered wings (such as the modern orders *Lepidoptera, Trichoptera, Hymenoptera*, and *Diptera*). 3. HEMIPTERA, comprehending the modern orders *Hemiptera, Homoptera, Orthoptera*, and *Dictuoptera*. 4. APTERA, including the orders of insects now named *Aptera, Thasynura*, and *Anoplura*, as well as the classes *Crustacea, Myriapoda*, and *Arachnoida*, and part of the classes *Vermes* and *Echinodermata*. In this latter order, he by no means deviated from the received opinions of his time. In the subsequent editions of this work, the Vermes and Echinodermata are separated, and constitute, with the true Mollusca, and the Entozoa, his class Vermes. See the year 1767, under which head, when speaking of his twelfth edition, his final views will be duly noticed.

In 1736, all the works of Swammerdam were put to press, entitled "Biblia Naturæ, sive Historia Insectorum, Belgiæ, cum versione Latina, H. D. Gaubii, et vita auctoris, per A. Boerhaave." The first volume appeared in 1737, and the second in the year following.

Lesser, in 1738, published a work entitled “ F. C. Lesser's Insecto-Theologia, oder Vernunft und Schriftmässiger Versuch wie ein mensch durch aufmerckaame Betrachtung derer sonst wenig geachteten, Insecten, &c. Frankfort und Leipzig.” 8vo. It was translated into French in 1742.

The folio work of L'Admiral, entitled “ Naawkeurige Waarneemingen van Gestaltvermisselende gekorwene Diertjes,” was published in Amsterdam. It contains a series of highly finished etchings, some of which have been copied by Harris, in his Aurelian. This work is confined to the insects of Europe, and contains figures of about fifty of the larger species, principally of Lepidoptera, which are represented in various attitudes, with branches of the plants in which their larvæ feed, accompanied, in some instances, with figures of their larvæ and pupæ. Most of the copies contain but twenty-five plates, and five pages of letter press; but we have seen one copy containing thirty-two plates, and twenty pages of description.

In 1741, Schæffer published his “ Icones Insectorum circa Ratisbonam Indigenorum,” in three volumes quarto, the plates being coloured. The classification of this author differs from that of Linné, and approaches to that proposed by Geoffroy in some points. He divided insects into seven orders, which he termed classes: 1. *Coleoptero-Macroptera*, those with their elytra crustaceous through their whole length, and extending beyond the abdomen when closed. 2. *Coleoptero-Microptera*, those with crustaceous elytra shorter than the abdomen. 3. *Coleoptero-Hymenoptera*, such as have their elytra half crustaceous, or becoming, towards their extremities, membranaceous. 4. *Hymeno-Lepidoptera*, insects with transparent or membranaceous wings, imbricated with scales. 5. *Hymeno-gymnoptera*, those with four naked membranaceous wings. 6. *Diptera*, insects with two wings. 7. *Aptera*, those without wings.

Lesser's Insecto-Theologia was translated by Lyonnet a la Haye into French in 1742, 8vo, entitled “ Theologie des Insectes, ou Demonstration des Perfections de Dieu dans tout ce qui concerne les Insectes.” The views of the author and translator are to promote the glory of God, nor do either of them attempt to establish any new entomological fact, but have directed their attention to the relating of such anecdotes relative to the natural history of insects, as could be rendered a convenient medium for the theological remarks with which the pages abound. To the entomologist the work is useless, as the remarks are often erroneous; but, as a theological publication, it doubtless had a useful tendency at the time in which it appeared. One of the best chapters relates to the abuse of inquiries about insects in theology, in which several of the fables invented by the Rabbis concerning the erection of Solomon's temple, &c. as well as the legends of Catholic superstition, equally fraught with folly, are most successfully combated.

Detharding, also, in the same year, published a small treatise relating to the larvæ of moths, entitled “ Disquisitio Physica Vermium in Norvegia qui nova visi.”

George Edwards, in 1743, published the first volume of his “ Natural History of Uncommon Birds, and of some other rare and undescribed Animals.” London, 4to. Three other volumes appeared before 1752, in which several insects are figured.

In 1744, at Stockholm, was published by De Geer, an interesting little work in octavo, entitled, “ Tal om nyttan, som Insectere othderas sharshadande, tilskynda oss,” pointing out the advantages of cultivating the natural history of these animals. It is, as far as we know, the oldest work on this subject.

In 1745, at Stockholm and Upsal, by Linnæus, a small octavo volume, entitled “ Ölandska och Gothländska Resa förrättad är.”

In 1746, “ Der Montalich-herausgegebenen Insecten Belustigung,” by Rösel of Nuremberg, a man of genius, who was by profession a miniature-painter. The work is in quarto. Two other volumes appeared in 1749 and 1755. To these a fourth volume was added by a relation (Kleemannir) after his death in 1761; and since that period, Kleemanahus published three other parts.

In 1747, a tract explaining the advantages arising from the study of insects, entitled “ Dissertatio de Usa Cognitionis Insectorum,” was published by C. F. Menander.

John Gould, in the same year, published, in London, “ An account of British Ants.”

And Ba[illegible] published, in Paris, his “ Abrégé de l'Histoire des Insectes, pour servir de suite à l'histoire naturelle des Abeilles.” Paris. In two volumes duodecimo.

Adrian Gadd, too, published in quarto, “ Observationes Physico-Œconomicæ, in Septentrionali prætura territorii superioris Satagundiæ collectæ. Dissertatio Præside C. F. Menander, Aboæ,” an interesting tract, explaining the advantages arising from the study of natural history.

In 1748, was published in London, by J. Dutfield, six numbers of “ A Natural History of English Moths and Butterflies.”

And two small tracts, by T. C. Hoppe, “ Antwort-Schreiben auf Hern Schreibers zweifel; Gera.”—“ Eichen Weiden und Dorrosen;” Leipsic.

In 1749, Linnæus published “ Skänska Resa.”

And, in the same year, or perhaps earlier, the work of Benjamin Wilks, entitled “ The English Moths and Butterflies, together with the Plants on which they feed, and are usually found.” The plates which appeared first bear no date. The greater portion of this publication is copied from the first volume of Rösel, from Albin, Merian, and other writers of his day; but this imposition on the public was not discovered in England; it was first pointed out by Rösel, in the third volume of his “ Insecten Belustigung.” Wilks also published “ Twelve new designs of Butterflies,” a work of no use to science, although sometimes quoted by writers on Entomology.

In 1752, Dr Hill, in his “ History of Animals,” London, divides insects into three classes; the first *Apteria*, includes all insects without wings; the second *Pteraria*, is devoted to the winged insects; the third *Gymnanthridia*, comprehends those with soft and naked bodies.

De Geer also, in this year, published the first volume of his invaluable work "Memoires pour servir à l'Histoire des Insectes," at Stockholm, which was received with every demonstration of praise to which its merits entitle it. From the testimony of the author's abilities, afforded by this volume, the continuation was expected with impatience; but nine years elapsed before the second volume appeared, and it was altogether twenty-six years from the commencement to its termination. It was completed in 1778, in which year the labours of its author closed with his life. He was author of several papers in various Transactions, which we shall notice in their proper places.

In the same year, Linnæus published two dissertations at Upsal, "Miracula Insectorum," and "Noxia Insectorum." The latter of these is very valuable, from the object in the contemplation of the author; and the first is not destitute of merit.

Scopoli, in the year 1753, produced his "Entomologia Carniolica," in which he distributes all the insects of which he treats into orders, genera, and species, nearly after the manner of Linné. As a systematic work, this publication is of little importance, in other respects it is valuable.

In this year also, "Novæ Insectorum Species, R. J. Uddman. Aboæ." 4to.

In the year 1754, Kalm, a learned botanist, published a paper on a species of Cicada, in the Swedish language, but we are unacquainted with its title.

In 1756, in folio, "Brown's Civil and Natural History of Jamaica.

F. Hasselquists published his "Iter Palæstinum" at Stockholm.

In this year, an English translation of one of the works of Swammerdam was published in London by Thomas Fleoyd.

In 1759, "Caroli Linnæi Animalium Specierum, &c. in formam Enchiridii, Ludg. Bat." 8vo.

In 1760, "Caroli a Linné Amœnitates Academicæ. Holmiæ." Volume V. 8vo.

In 1761, Linnæus produced his "Fundamenta Entomologiæ," being an introduction to the study of the science.

In this year likewise an interesting work, "Insecta Musei Græcensis," was given to the world by Nicolaus Poda, containing an account of the Insects of Greece, after the Linnean manner.

J. H. Sulzer, in the same year, produced an introductory work to the study of Insects, in quarto, illustrated by several plates, under the title, "Die Kennzeichen der Insekten nach Anleitung der Ritters, Karl Linnæus, durch 24 Kupfertafeln erlautert, und mit derselben naturlichen geschichte begleitet." Zurich.

And Linnæus his "Fauna Suecica editio altera auctior."

Also Martinus Thrane, "Prodromus Insectorum Siællandicæ, Hafniæ." 8vo.

Sepp, in 1762, began his "Beschonaring per Wondern Gods in de Minsgeachte schepzelen of Nederlandsche Insecten," which is dedicated to Dutch Lepidopterous Insects. The plates are very numerous, and admired for their peculiar neatness, being engraven in the dot manner, with very considerable delicacy and elegance.

In this year, a most valuable systematic work by Geoffroy was published in Paris, and demands the attention of every entomologist, to whom the possession of it is indispensable. It is entitled, "Histoire Abrégée des Insectes," and divides Insects into six classes, 1. *Coleoptères*; 2. *Hemiptères*; 3. *Tetraptères* à ails nues; 4 *Tetraptères* à ailes farineuses; 5. *Diptères*; and, 6. *Aptères*. In the distribution of the genera, he has made much use of the number of joints composing their tarsi.

L. T. Gronovius published, in 1763, in folio, "Zoophylaceum." Three fasciculi only appeared.

Linnæus again appeared before the public, and produced his "Museum Ludovicæ Ulricæ Reginæ. Holmiæ, 1764." 8vo.

"M. T. Brünnich Entomologia, Hafniæ, 1764." 8vo.

"O. F. Muller Fauna Insectorum Fridrichsdalina, sive Methodica Descriptio Insectorum agri Fridrichsdalensis, &c. Hafniæ et Leipsiæ." 8vo.

Also, J. C. Schæffer's "Abhandlungen von Insecten. 3 Bande. Regenburg." 4to.

And the second part of "Zoophylacium Gronovianum," containing descriptions of about six hundred insects, with synonyms after the Linnean system, accompanied by four illustrative plates. Leyden. Folio.

In 1766, Schæffer published at Regensburg, "Elementa Entomologiæ," containing 132 plates, illustrating the principles of his system; and an additional section with two plates, describing the manner of catching, feeding, and examining insects. He was author of another work on the same subject, entitled, "Zweifel und Schwurigkeiten, welches in der Insectenlehere annoch vorwalten," which was published at Regensburg, but we are ignorant of its date.

Pallas, in 1767, published at Berlin, in 4to, the first fasciculus of his "Spicilegia Zoologica quibus nova informis et obscuræ Animalium species Iconibus, Descriptionibusque atque Commentariis illustratur;" a very valuable work. Several other fasciculi were published before 1780, when the last made its appearance.

In the same year, the twelfth edition of the "Systema Naturæ" of Linnæus was produced; and as it was the last of that celebrated naturalist, we shall lay before our readers his entomological arrangement. He divided insects into seven orders, deducing his characters from their wings, as follow:

Order I. Coleoptera (from κολεὸς, a sheath, and πτερὸν, a wing). Insects with four wings, the anterior of which are crustaceous, and shut together, forming a longitudinal suture down the back. (*Beetles.*)

Order II. Hemiptera, (from ἥμισυ, half, and πτερὸν, a wing). These insects with their upper wings half crustaceous, and half membranaceous, or of a matter intermediate between leather and membrane. (*Bugs, Locusts, Cockroaches.*)

Order III. Lepidoptera (from λεπὶς, a scale, and πτερὸν). Insects having four wings, imbricated with scales. (*Butterflies, Moths.*)

Order IV. Neuroptera (from νεῦρον, a nerve, and πτερὸν). Insects with four transparent naked wings, reticulated with nerveures. (*Dragonflies, Phryganeæ.*)

Order V. Hymenoptera (from ὑμὴν, a membrane, and πτερὸν). Insects with four naked membranaceous wings. (*Bees, Sawflies.*)

Order VI. Diptera (from δὶς, two, and πτερὸν). Insects with two wings. (*Gnats, Flies, Gadflies, &c.*)

Order VII. Aptera (from ἀ, without, and πτερὸν). —(*Fleas, Lice, Spiders, Mites, Centipieds, Crabs, &c.*)

The great perspicuity of Linnæus's system of entomology arose from its author having made choice of the most obvious marks which insects afford, for the leading distinctions of his orders. In the construction of his genera, he has taken his characters from the parts of the head alone, especially from the form of the antennæ or horns; these parts being subject not only to a great variety in their appearance, but being also very prominent organs in most insects. That there are other characters, which, in the opinion of modern entomologists, ought not to be neglected, the reader must be perfectly aware; and although these may be too minute for the superficial observer, yet to the man of science, who wishes to study the philosophy of classification, there can rest no doubt as to the superiority of the modern views, which take into consideration every possible character, external as well as internal. The simplicity of the general distribution proposed by Linnæus, the celebrity of his name, and the princely patronage under which he wrote, conspired, with other favourable circumstances, to render the science more universally cultivated, admired, and respected about his time, than it appears to have been at any former period. Much credit is undoubtedly due to this great man for his entomological labours. We must not, however, be so unjust as he was, and neglect to acknowledge the merits of his predecessors, who wrote under less favourable circumstances, but nevertheless excelled in this department of science; and to whom Linnæus stands in a very high degree indebted. In the works of Aristotle and Pliny, in those of Aldrovandus and Swammerdam, as well as in those of our countrymen, Ray, Willoughby, Lister, and various others (whose works we have noticed), we perceive, with some variations, the grand outline on which he has founded his arrangement. It was from these valuable sources that he gained the materials, from which he has selected, with profound judgment, and the greatest success, the valuable matter, carefully and industriously separating the dross. The characters of his orders and genera are to be found in several earlier publications, as are descriptions of many of the species. But he has concentrated these scattered rays of science, with so much skill and industry, that we must admit, that to him the science is indebted for that firm foundation on which it now rests. His style throughout is concise and expressive, but in many instances it is so laconic, that it is impossible even to guess at the animals described.

Bomare published in 1768, "Dictionnaire Raisonné Universel d'Histoire Naturelle, Paris." 4to.

In 1769, in three volumes 4to, "Icones Insectorum Circa Ratisbonam Indigenorum, &c. Regensburg," by Schæffer.

Dr J. Berkenhout published, in the same year, the first edition of his "Outlines of the Natural History of Great Britain." That portion treating of Insects is extremely limited; he has enumerated no more than six hundred species, which are arranged after the Linnean method. Notwithstanding its defects, this little book has materially advanced the study of Entomology in Great Britain.

P. S. Pallas, this year (1770), published his "Spicilegia Zoologica. Berolini." 4to. Eight numbers.

And J. R. Forster published at Warrington, in 8vo, "A Catalogue of British Insects," a mere list of Latin names, amounting to about 1000 species, the greatest number hitherto enumerated. This was intended as a Prodromus to a general work on the Insects of Britain, as we learn from the preface, where the author offers duplicates in exchange for any not in his collection.

D. Drury, also this year, produced a work in one volume, containing descriptions in French and English, with an index of Linnean names, illustrated by coloured copperplates, entitled, "Illustrations of Natural History, wherein are exhibited Figures of Exotic Insects," &c. The plates form a miscellaneous assemblage of the more beautiful exotic insects, which the extensive collection of the author afforded. Three years after the publication of the first volume, a second came out; and the third, which concludes the work, appeared in 1782. Besides those figured and described in the three volumes published, the extensive cabinet of Mr Drury contained many choice specimens, reserved as materials for a fourth, amongst which were a vast number of curious species, collected in the interior of Africa, and other parts of the world rarely visited by Europeans, the introduction of which would have rendered this volume of much greater interest than any of the preceding. Mr Drury's cabinet contained about 11,000 species of insects (in his time the largest collection), which he obtained by transmitting printed directions in various languages for gathering and preserving insects, offering sixpence *per* insect "for all, from the size of a honey-bee upwards." This museum was disposed of by public auction, and produced six hundred pounds. All the British species were purchased by Mr Donovan.

In 1771, John Reinhold Forster produced "Novæ Species Insectorum Centuria," the avowed purpose of which was to describe an hundred species of insects, not mentioned in the latest work of Linnæus. The greater number of these are coleopterous insects, partly indigenous, some from China, and others from South America. These, with the exception of the genera Cistela and Anthribus, which are adopted from Geoffroy, are arranged after the manner of Linnæus. Many of the species were unknown to Linnæus; but some few had previously been made known to the world by the works of Schæffer and Drury. Forster was one of the naturalists who accompanied Captain Cook in his voyage round the world.

The "Mantissa Plantarum" of Linnæ, in which several insects not mentioned in his former works are described, appeared at Holm, this year, in octavo.

In 1772, Curtis produced a translation of the "Fundamenta Entomologiæ" of Linnæ, which tended materially to advance the study of entomology in this country.

M. T. Brunnich produced his " Zoologiæ Fundamenta, Hafniæ et Lipsiæ, in 8vo.

" Icones rerum Naturalium, &c. par le Professeur Arcanius. Copenhague, 1772." 4to.

Also " Introduction aux Observations sur la Physique, &c. par L'Abbé Rozier." Vol. I. and II. Paris.

This journal, which we shall henceforward term " Journal de Rozier," is now continued monthly under the title of " Journal de Physique." The above two volumes contain, " 1. Observations sur le Notopède, par E. Weiss. 2. Histoire des Charansons, avec des moyens pour les détruire, &c. 3. Descriptions des Plusieurs Insectes inconnus jusqu' à ce jour." In this memoir will be found figures of species, considered by the naturalists of the present day as recent discoveries.

In 1773, Kahn published a tract relative to the mode of preserving and catching insects, entitled, " Kurze anleitung Insecten zu sammlen."

In the same year, T. P. Yeats published " Institutions of Entomology," an useful work, being a translation of the characters of Linnean orders and genera, collated with three other systems; namely, those of Geoffroy, Scopoli, and Schæffer. It contains many original observations, but is very defective in the comparison drawn between the systems of Scopoli and Linnæ.

In this year, too, the account of a tour made by the celebrated Russian naturalist Pallas appeared, entitled, " P. S. Pallas Reise durch Verschiedene Provizen des Russichen Reichs, St Petersburgh," which has been translated into Latin and English.

In the same year, Dr J. Hill published a " Decade of curious Insects, some of them not described before, shown of their natural size, and as they appeared through a microscope," &c. which is illustrated with ten quarto plates, in which the figures are sometimes immensely magnified, and far from correct. The accounts are in English, and are accompanied with observations on their economy.

In 1774 was published at Amsterdam, in folio, by Jacob L'Admiral, " Veranderingen van Veele Insecten."

And " J. L. Tagebuch der Reise durch verschiedene Provinzen der Russischen Reichs, Alenburgh." Two other volumes were published before 1783.

The Journal de Rozier, for this year, contains, 1. " Observations sur les Mouches communes, par Blondeau. 2. Mémoire sur la manière d'elever les larves des Papillons, &c. par M. Nicolas. 3. Lettre de M. Bonnet, sur les moyens de conservir diverses espèces d'Insectes, &c.

In 1775, J. C. Fabricius, a pupil of Linnæus, published a new system of Entomology, under the title " Systema Entomologiæ," in which the principles of a new mode of classification are, for the first time, developed. He has taken the essential characters of his classes and genera, from the parts of the mouth (Instrumenta Cibaria), which has given to his classification the title of *Cibarian System*. In this work, he has disposed all Entoma into eight classes, viz. *Eleutherata*, *Ulonata*, *Synistata*, *Agonata*, *Ugonata*, *Glossata*, *Rhyngata*, and *Antliata*. In this general arrangement Fabricius has been followed by but few; but his mode of distinguishing the genera it still retained by all; and by the followers of Latreille, it is combined with other essential characters, such as organs of locomotion, &c. He gained so much reputation by this work, that he prosecuted his labours with increased ardour, and acquired the rank of the first entomologist of his age. We shall notice his later system in proper order.

Also, " Descriptiones Animalium, &c.; quæ in Itinere Orientali observavit, Petrus Forskal. Post mortem auctoris, edidit Carsten Niebuhr."

Moses Harris also published a little pamphlet, entitled, " The English Lepidoptera, or Aurelian's Pocket Companion," &c. London; an alphabetical catalogue of the larger Lepidoptera, collected by its author in England. This little tract, although apparently insignificant, has materially contributed to the practical study of entomology in Britain. The Linnean names, as far as they were known to him, were added, and the time and place of the appearance of the insects in their different states are concisely given in columns. A frontispiece is added, explaining the terms used in the description of the insects of this order.

" Dissertazione seconda su de' Timpanetti dell' udito scoverti Nel Granchio Paguro e Sulla Bizzarra di lui vita, del P. A. Minasi. Napoli, 1775." 8vo. We received this rare work as we were correcting the press; it is therefore impossible to give an analysis of its contents.

The Journal de Rozier, for this year (Vol. V. and VI.), contains, " Trois Mémoirs sur les Abeilles," &c. par M. Bonnet; and Vol. VIII., for 1776, contains, " Essai sur la Fourmi, par M. Barboteau."

In the same year, Peter Brown, In his " New Illustrations of Zoology," figured several insects.

And J. H. Sulzer published, in quarto, his " Abgekurzte Geschichte der Insecten, Winterthur."

The " Genera Insectorum" of Fabricius appeared in this year.

Also, " Beytrage zur Naturgeschichte von Franz, von Paula Schrank, Leipzig." 8vo.

O. F. Muller produced his " Zoologiæ Danicæ Prodromus, &c. Hafniæ," which is an useful book.

A valuable work was published at Halle in octavo, by J. Schroter, named, " Abhandlungen uber verschiedene Gegenstande der Naturgeschichte;" a succeeding part appeared in 1777.

Also, an useful book in quarto, entitled, " Systematisches Verseichnis der Schmetterlinge der Wienergegand, &c. Wien."

Scopoli, in 1777, produced his " Introductio ad Historiam Naturalem." In this work, insects are divided into five groups, under the singular appellations of, 1. *Swammerdami-lucifuga*; 2. *Geoffroy-gymnoptera*; 3. *Roeselii-lepidoptera*; 4. *Reaumurii-proboscidea*; 5. *Frischii-coleoptera*. In this manner he identifies each tribe with the name of the author who has, in his opinion, been most successful in the explanation of that to which his name is attached.

In this fertile year, J. A. E. Goeze began his extensive systematic work, called, " Entomologische beytrage zu des Ritters Linné zwoffen Ausgabe des Natur Systems," &c. which was continued progressively in parts, till 1783, in octavo.

Esper also produced in Germany the first part of his valuable work on Lepidoptera, entitled, "Die Schmetterlinge in Abbildung nach der Natur mit Beschreibungen," illustrated by several plates; a second part appeared in 1779, and, before 1786, two other parts also were published.

The Journal de Rozier, for this year (Vols. IX. and X.) contains, 1. "Suite de l'Essai sur la Fourmi, par M. Barboteau. 2. Description d'une Lepture, et d'une espèce de Scorpion aquatique;" and Vol. XI., for 1778, contains, "Observations sur la production des pattes des Crabes, par M. de Badier."

At Berlin, during the same year, P. S. Pallas published in quarto, "Naturgeschichte Merkwürdigen Thiere, in welcher Vornehmlich neue und unbehannte Thierarten durch kupferstriche, Beschreibungen und Erklärungen erläutert werden."

And, Paul Czempinsky, in octavo, "Totius Regni Animalus Genera."

Also, in quarto, "Nomenclatur und Beschreibung der Insecten in der Graffschaft Hanau-Münzenberg, von J. A. B. Bergstræsser."

"Magazin für die Liebhaber der Entomologiè Heramsgegeben, von. J. G. Fuesly, Zurich und Winterthur."

"Versuch einer Naturgeschichte vom Livland, Entworfen, von J. L. Fischer, Leipzig." 8vo.

Moses Harris also published his "Aurelian, or Natural History of English Insects, namely, Moths and Butterflies, London." 4to.

Lastly, "J. C. Fabricii Philosophia Entomologica;" a small work, which, with all its faults, is indispensably necessary to the library of the scientific Entomologist.

In 1779, Pieter Crammer published a work on exotic Lepidoptera, entitled, "De vit Landsche-Kapellen, Voorkomende in de drie Waereld deelen Asia, Africa, en America." This part, with the continuation published in 1782, consists of four quarto volumes.

And, in the same year, another very extensive work, devoted also to Lepidoptera, named, "Papillons, d'Europe peints d'après Nature, par Ernst."

Also, in octavo, "Anfangsgründe der Naturgeschichte, von N. G. Leske. Leipzig."

The Journal de Rozier, for this year, Vol. XIII., contains, "Observations sur les Œufs des Papillons, par J. Bernoulli."

A very valuable little book, in one volume octavo, on the animals of Greenland, was published in 1780, viz. "Othonis Fabricii Fauna Grœnlandica. Hafniæ et Lipsiæ."

"Lettres sur les Truffes du Piémont," par le Comte de Borch. Milan, 1780. 8vo. Contains Observations on the insects that destroy truffles.

"Hydrarchnæ quas in aquis Dariæ palustribus detexit, descripsit, &c. Otho Fredericus Müller. Lipsiæ, 1781." A very valuable work, with good figures of the species of the genera Hydrachna and Elaïs.

"J. C. Fabricii Species Insectorum, Hamburgi et Killonii." Two volumes octavo.

F. P. Schrank produced a descriptive catalogue of the Insects of Austria, called, "Enumeratio Insectorum Austriæ Indigenorum," which has since been rendered into German by Fuesly.

Johann Nepomuk von Laicharting, in this year, published at Zurich, the first part of his catalogue of the Insects of the Tyrol, "Verzeichniss und Beschreibung der Tyroler Insecten;" a second part appeared in 1784. He adopts a system very distinct from that of Linnæus. Insects are by him disposed into ten groups, characterized from various parts of the body, and are named, *Scarabæoïdes*, *Grylloïdes*, *Cimicoïdes*, *Papilionoïdes*, *Libelluloïdes*, *Vespoïdes*, *Muscoïdes*, *Cancroïdes*, *Aranoïdes*, and *Oniscoïdes*.

"Icones Insectorum præsertim Rossiæ, Siberiæque, peculiarium, quæ collegit et descriptionibus illustravit, Petrus Simon Pallas, M. D. Erlangiæ, 1781." One volume 8vo.

Thunberg, too, published at Upsal, the first part of his "Museum Naturalium Academiæ Upsalensis," to which twenty other parts, and an appendix, were added before 1800.

"Beitrage zur Insektengeschichte, &c. W. Knoch, Leipzig." 8vo.

James Barbut published, in the same year, an elementary book, entitled, "The Genera Insectorum of Linnæus, exemplified by various specimens of English Insects," London. As an illustration of the Linnean System, this work may not be uninteresting to the English reader, but his views are too limited to admit of even mere general utility. Its author does not seem to have been aware of the vast improvements the science had undergone on the Continent, in the interval between the publication of Linnæus's last work, and the time he wrote; and has, therefore, drawn no comparisons between them, which, without innovation, must have placed the science in a more lucid point of view. It is to the silence of English writers, either arising from want of information, from sentiments of illiberality, from jealousy or negligence, that we must ascribe the very low state of entomological (and indeed of every branch of zoological and zootomical) knowledge in Britain, at the present period.

Moses Harris, in 1782, published his "Exposition of English Insects, &c." illustrated by fifty-one copperplates, in 4to, in which he has given figures of about 500 species. The descriptions are in French and English; the specific names in Latin, but many of them of a nature by no means to be tolerated, such as *Apis Audeo*, &c.

In the Transactions of the French Academy we find a paper by Morand, entitled, "Memoire sur les Vers de Truffes, et sur les Mouches qui en proviennent."

"Versuch eines Diarium über die Œconomie Mancher Insecten im Winter, von J. S. Semler."

Another interesting work appeared this year, "Nues Magazin für die Liébhaber der Entomologie, Hérausgegeben, von J. C. Fuesly, Winderthur." 8vo.

In 1783 appeared "C. Lib. Bar. De Geer. Genera et Species Insectorum e generosissimi auctoris scriptis extraxit, A. J. Retzius. Lipsiæ, 1783." 8vo. In this work, insects are divided into fourteen groups, under the titles, *Lepidoptera*, *Alinguia*, *Neuroptera*, *Hymenoptera*, *Syphonata*, *Dermoptera*, *Hemiptera*, *Coleoptera, Halterata, Proboscidea, Suctoria, Arcenata, Atrichelia,* and *Crustacea.*

In the same year, W. Curtis published an interesting little pamphlet, "A Short History of the Brown-Tail Moth," the caterpillar of which had appeared in such immense swarms in the fields surrounding London, during the summer of 1782, and despoiled so many trees of their foliage, as to create apprehensions of the total destruction of the whole vegetable kingdom, and to spread such an alarm throughout the whole population of that vast metropolis, that prayers were ordered to be read in all the churches to avert the supposed impending calamity The object of this tract is to point out the absurdity of these apprehensions, and to show, that corn and grass, not being the food of these voracious animals, would escape their attack.

In 1784, J. A. B. Bergstræsser published his elementary work, in octavo, entitled, "Entomologia Scolarum in usu Concinnata."

Thunberg, in this year, published his "Dissertatio sistens Insecta Suecica."

And Herbst produced his work, entitled, "Kurze Einleitung zur Kenntniss der Insecten, Berlin." 8vo.

The "Journal de Rozier" (Vols. XXIV. and XXV.) contains, 1. "Mémoire sur l'Histoire des Abeilles, par l'Abbé Ray." 2. "Dissertation sur la sensibilité des Insectes, précédée de quelques observations sur la Mante, par l'Abbé Poiret;" and Vols. XXVI. and XXVII., for 1785, contain, 1. "Moyen simple de dessécher les larves pour les conserver dans les collections Entomologiques à côté des Insectes qu'elles produisent, par D'Antic." 2. "Description de quelques individus monstrueux de la Péduculaire des Bois, par Reynier."

"Entomologia Parisiensis, sive Catalogus Insectorum quæ in agro Parisiensi reperiuntur, secundum Methodum Geoffrœanum, edente A. F. De Fourcroy." Two volumes 12mo.

Matthew Martyn published this year in Exeter, his "Aurelian's Vade Mecum." The Insects are whimsically arranged, according to the Linnean classes and orders of plants on which they feed.

"Historia naturalis Curculionum Sueciæ, auctore Gabriel Bonsdorff, &c. Upsaliæ." 4to.

"Natursystem aller Bekanten in und Auslandischen Insecten, &c. von Carl. Gustaf. Jablonsky, Berlin, Fortgesetzt, von J. T. W. Herbst."

In 1786, Xavier Wulfen published an account of the Insects inhabiting the Cape of Good Hope, entitled, "Descriptiones quorandam Capensium Insectorum, Erlangæ."

The "Journal de Rozier," for this year (Vols. XXVIII. and XXIX.), contains, 1. "Observations sur des Crevettes de Rivière phosphoriques, par MM. Th[illegible]s et Bernard." 2. "Recherches sur les Sauterelles et sur les moyens de les déstruire, par M. Baron;" and Vols. XXX. and XXXI., for 1787, contain, 1. "Observations sur la durée de la vie de certains Insectes, par M. Riboud." 2. "Mémoires sur quelques Insectes de Barbarie, par l'Abbé Poiret." 3. "Observations sur les effets de la figûre de l'Arraignée-Crabe des Antilles, par M. Arthaud." 4. "Decription de la Bête à mille pieds de St Domingue, par le même." 5. "Lettre de M. Bruyère, à M. Thouin, sur un nouvel Insect." 6. "Mémoire sur quelques Insectes, par M. de la Martinière." 7. "Lettre de le Comte de Razoumousky, sur une Araignée."

Dominicus Cyrillus published this year a folio work on the Insects of Naples, entitled, "Entomologia Neopolitana."

A curious little tract, on the Gad-fly, was published in Leipsic, by J. S. Fischer, entitled, "Observationes de Œstro ovino atque bovino factæ."

"J. C. Fabricii Mantissa Insectorum, Hafniæ." Two volumes 8vo.

"V. Petagnæ Specimen Insectorum Ulterioris Calabriæ, Francofurti et Moguntiæ." 4to.

"Disputatio inauguralis de Coccinellæ Natura, Viribus et Usu, A. J. G. Linck. Lipsiæ." 4to.

John Adams published "Essays on the Microscope," in quarto, London.

The "Journal de Rozier," Vol. XXXIII., for 1788, contains, 1. "Extrait d'un Mémoire lu à l'Académie des Sciences, sur les parties de la bouche des Insectes, par M. Olivier;" and Vols. XXXIV. and XXXV., for 1789, contain, 1. "Recherches sur la Chenille Processionaire du Pin, par M. Dorthes." 2. "Mémoire sur quelques espèce de Charonsons de la Guyenne Françoise, par M. Sonini de Monoucour."

A series of Letters, on the important subject of the cochineal insect (which had been discovered at Madras a few years before), from James Anderson, addressed to Sir J. Banks, from Madras, were published. Two other letters have been published since.

In the same year, Swederus published a monograph on that curious and interesting genus *Cerapterus,* in a Memoir, entitled, "Beskrifuing poa elt nytt genus ibland insecterna, hörande til Coleoptera."

The work of M. B. Borkhausen, on the Lepidoptera of Europe, appeared at Francfort, entitled, "Naturgeschichte der Europaischen Schmetterlinge nach Systematischer ordnung."

J. F. Gmelin published his edition of the Linnean *Systema Naturæ.* The Entomological part is comprized in three parts, and was published at Leipsic. The editor is considerably indebted to the writings of Fabricius; and, although he rejects his classification, yet he has copied the species, and incorporated them with the Linnean genera, which he has divided into families, answering to the Fabrician genera, and has, by this means, very materially augmented and improved the original work of Linnæus; although he has committed a vast number of the most inexcusable blunders, especially in his quotations and references to plates. He has, in many instances, described the same species twice or three times, under different names. But we are surprised that his errors are so few, when we consider that he was but a closet compiler.

In this year also was published, in Leipsic, a work, entitled, "Nützliches Allerley aus der Natur und dem gemeinen Leben für allerley Leser, von J. A. E. Goeze." 8vo.

Mr Thomas Marsham wrote the article Entomology in " Hall's Encyclopædia," which is illustrated by three plates. In this paper he briefly explains the Entomological System of Linnæus, and mentions the names of several authors of eminence; he likewise explains the method of collecting and preserving insects..

In this year, too, J. J. Römer published his " Genera Insectorum Linnæi et Fabricii, Iconibus Illustrata, &c. Vitaduri Helvetiorum." 4to. This work contains thirty-seven explanatory plates, nearly all of which had previously constituted the work of Sulzer.

The celebrated Olivier published this year the first part of a very voluminous and valuable work, entitled, " Entomologie, ou Histoire Naturelle des Insectes, avec des caractères génériques et specifiques, &c. Paris." 4to. From its title, it would seem that the author intended to have treated on every class and order; and, in conformity with the first part, to have illustrated the whole with figures. He, however, has confined the book entirely to the illustration of the Coleoptera, which was rendered as complete as possible, and as a work of reference, is one of very great utility.

G. Paykull produced in this year, at Upsal, " Monographia Staphylinorum Sueciæ," in octavo.

And C. de Villers published, at Lyons, a small work, under the title, " Linnæi Entomologia, &c. curante et augeate C. de Villers, Lugduni," 8vo. In which the author has availed himself of the works of *Scopoli, Geoffroy*, De Geer, and Fabricius.

And at Leipsic, in Octavo, " Anfangsgründe der Naturgeschichte von N. G. Leske."

In 1790, some remarks on the genus Melolontha were published in the " Journal fur die Entomologie," &c. vor D. J. Mayer.

In the same year, a catalogue of the Insects of Bohemia, entitled, " J. D. Preysler, Verzeichniss Böhmischer Insecten, Prag." 4to.

And " Fauna Estruca, sistens Insecta, quæ in provinciis Florentina et Pisana præsertim collegit, Petrus Rossius, Liburni." 4to. The genus *Xenos*, the type of the new order *Rhipiptera*, is first made known in this work.

Also, " Dissertatio Historico-naturalis, ignotas Insectorum species continens; auctore Conrad Quesnal, Lundæ." 4to. This author is also the author of two tracts, but we are ignorant of their dates; the first is on Papilio, entitled, " Beskrifningar öfer 8 nya Svenska, Dagfjarillar;" the second on a moth, " Beskrifningar öfer en y Nattjaril."

G. Paykul too produced his " Monographia Caraborum Sueciæ."

L. G. Scriba likewise published two works, " Beytrage zu der Insecten Geschichte; Frankfurt." And " Journal für die Liebhaber der Entomologie; Frankfurt."

And " Insecten Kalender, von N. J. B. Mainz." 8vo.

The Journal de Rozier, Vol. XXXVI., contains a paper, entitled, " Notice sur un phénomène occasioné par une espece de Fourmi nommée par Linnæus *Formica* nigra; par M. Dorthes."

Lastly, the first volume of a great compilation on Zoology, entitled, " Vivarium Naturæ, or the Naturalist's Miscellany, by G. Shaw, the figures by F. Nodder." A volume was produced annually for twenty-four years, when the author died. Several gaudy insects are figured in this work.

In 1791, the first volume of the " Transactions of the Linnean Society of London" appeared, and contained the following papers: 1. " On the *Phalæna Bombyx Lubricepeda* of Linnæus, and some other species allied to it; by T. Marsham, Esq." 2. " Some observations on the Natural History of *Curculio Lapathi* and *Silpha grisea* of Linnæus; by W. Curtis, Esq." 3. " Account of a singular conformation in the Wings of some Moths, by Esprit Giorna." 4. " Descriptions of two new species of *Phalæna*, by L. Bosc;" and, lastly, under the head of extracts from the minute book, we find mention of a new Baprestis, communicated by Mr Dryander.

In the same year, " Neuestes Magazin für die Leibhaber der Entomologie, herensgegeben von D. H. Schneider; 5 hefte. Straulsund." 8vo.

Likewise, " Alphabetisches Verzeichnis der Bischer Behaunten Schmeterlinge, &c. Von C. C. Jung. Marktbreit." 8vo.

Also, an interesting work on some Hymenoptera, entitled, " Naturgeschichte, Klassification und Nomenclatur der Insecten von Beinen, Wesgen und Ameisengeschlet. Frankfort am Main; von C. J. Ludwig." 4to.

In 1792, Edward Donovan published the first volume of his " Natural History of British Insects." 8vo. The work consists of eighteen volumes, which were published in successive years, and includes figures and descriptions of a considerable variety of species, being the most extensive elucidation of British Entomology that has hitherto been undertaken.

Thomas Martyn published in the same year, " The English Entomologist, exhibiting all the coleopterous insects found in England, including upwards of five hundred different species, the figures of which have never been given to the public; the whole accurately drawn and painted after nature, arranged and named after the Linnean system. London." 4to. Although this work is so frequently cited, the figures are nearly useless, and the text but indifferent.

J. C. Fabricius published in this year his " Entomologia Systematica." A supplement appeared in 1798, under which date we shall mention his latest systematic views.

And G. Paykull produced his " Monographia Curculionum Sueciæ."

Lastly, O. F. Müller published his celebrated work, " Entomostraca seu Insecta testacea quæ in aquis Daniæ et Norvegiæ reperit, descripsit et Iconibus illustravit, O. F. Müller. Frankfurti." 4to. In this volume, all the Entromostraca, which Linné had comprehended under the generic title *Monosculus* (excepting his cancer *salinus* and *stagnalis*), are arranged as follow:

I. MONOCULI. * *Univalves*. Gen. 1. Amynome; 2. Nauplius.
** *Bivalves*. Gen. 3. Cypris; 4. Cythere; 5. Daphnia.
*** *Crustacei*. Gen. 6. Cyclops; 7. Polyphemus.

II. Binoculi. * *Univalves.* Gen. 8. Argulus; 9. Caligus; 10. Limulus.
** *Bivalves.* Gen. 11. Lynceus.

G. W. F. Panzer, in 1793, published his "Beyträge zur Geschichte der Insecten. Erlang.;" and, in the same year, commenced the "Fauna Insectorum Germaniæ Initia, oder Deutchland Insecten." One hundred and nine numbers, each containing twenty-four plates, were published before the death of the author. In the following year, 1794, he published his "Entomologia Germanica. Pars I. Nuremberg." 8vo. Also "Fanunæ Insectorum Americæ Borealis Prodromus;" and edited "J. E. Voet Icones Insectorum Coleoptratorum, &c. illustravit G. W. F. Panzer. Erlangæ." 4to.

"Neuestes Magazine für die Libhaber des Entomologie herausgegeben, von D. H. Schneider. Stralsund." 8vo.

A second volume of the Transactions of the Linnean Society appeared this year; in which are the following Entomological papers: 1. "The History and Descriptions of four species of *Phalæna*, by Mr J. Beckwith." 2. "A new arrangement of the genus Papilio of Linnæus, by W. Jones." In this paper a new division, the *Romani*, is added, and the characters of the Linnean divisions are very much amended.

In the Journal de Rozier (which here, for the first time, appears under the care of J. C. Lamétherie), for this year, we find a paper by Monsieur Luce, entitled, "Description d'un Insecte Phosphorique."

In 1795 was published in Halle, in 8vo, "Entomologisches Bilderbuch für junge Insectensamler, von J. H. A. Dunker."

"D. H. Hoppe Enumeratio Insectorum circa Erlangani indigenorum, &c.; Observationibus Iconibusque illustrata, Erlangæ." 8vo.

"The Papilios of Great Britain, by W. Lewin. London." 4to. In this work the Butterflies of England, sixty in number, and all that were at that time discovered in England, are elegantly figured.

The "Gesellschaft Naturforschender Freunde zu Berlin," for this year, contains a paper entitled "Bescreibung einiger ostindischen Insectin, von Missionarius John in Tankebar."

P. A. Latreille, in 1796, produced his "Precis du caractéres des Genres," a work which commences a new era in the science of Entomology, and in which, for the first time, the distribution of Insects, Crustacea, &c. into families, is indicated. The genera are characterized by the modification of the organs of mastication. Throughout this volume we find the same acuteness of observation, that characterizes all the works of this, the first of Entomologists.

Mr John Francillon also published this year, "Description of a rare Scarabæus, from Potosi." The subject of this paper has been named *S. Macropus*, by Shaw. It forms the type of a new genus, the characters of which will be soon given to the world, by W. Macleay, Esq. a most accurate and learned entomologist, who is now occupied with examining the old genus Scarabæus of Linnæus, of which his father's cabinet contains about 2000 species, which he intends to arrange into natural families and genera.

The second volume of "Catalogus Bibliothecæ Historica Naturalis, Josephi Banks, Baroneti," by T. Dryander, comprehending the entomological works of that immense collection, appeared this year. The contents of this work are so admirably arranged, as to form a valuable bibliographical system of Entomological writers, down to the day of its publication.

"Monographia Bombyliorum Bohemiæ, Iconibus Illustrata, auctore J. C. Mikau, M. D. Pragæ."

In 1797 appeared, "Natursystem der Ungeflügelten Insecten, von J. F. W. Herbst. Erster Heft. Berlin." 4to. This volume contains the *Solpugæ*, *Phrynni*, *Thelephroni*, and *Opiliones*, which are illustrated by coloured figures.

"Illustratio Iconographia Insectorum quæ in Musæis Parisnis observavit, J. C. Fabricius. Auctore S. J. Coquebert." 4to.

"Mantissa Insectorum Iconibus Illustrata, &c. Fas. 1. auctore G. C. Reich, Norimbergæ." 8vo.

"The Natural History of the rarer Lepidopterous Insects of Georgia, collected from the Observations of M. J. Abbot, by J. E. Smith, M. D." This work is comprised in two volumes, with about an hundred plates, copied from the original designs made from nature by Mr Abbot, to whom the London collectors of insects are indebted for the greater portion of the Georgian insects contained in their cabinets. Eighteen volumes of insects, their larvæ, &c. and spiders, drawn by Mr Abbot, are now deposited in the British Museum, for the use of those engaged in the study of Entomology.

The third volume of the "Transactions of the Linnean Society of London," containing some interesting papers, appeared in the same year. 1. "Observations on some rare Insects, by W. Lewin." 2. "History of three species of *Cassida*, by the Rev. W. Kirby." 3. "Observations on the Economy of *Ichneumon Manifestator*, by T. Marsham, Esq." 4. "Observations on the Insects that infested the Corn in 1795, by the same." 5. A most interesting and valuable paper on "The *Œstrus* or *Gadfly*, by B. Clark, Esq."

In 1798, J. C. Fabricius published the supplement to his "Entomologia Systematica;" which presents to us his system in its latest state, and therefore deserves to be recorded here.

Class I. Eleutherata. Jaws naked, free, bearing palpi.

Class II. Ulonata. Jaws covered with an obtuse mouth-piece or galea.

Class III. Synistata. Jaws elbowed near the base, and connected to the lower lip.

Class IV. Piezata. Jaws horny, compressed, and generally elongated.

Class V. Odonata. Jaws horny and toothed; two palpi.

Class VI. Mitosata. Jaws horny, arched; no palpi.

Class VII. Unogata. Jaws horny, unguiculated.

Class VIII. Polygonata. Jaws many, within the lip.

Class IX. Kleistagnata. Jaws many, without the lip.

Class X. Exognata. Jaws many, outside the lip covered by the palpi.

Class XI. Glossata. Mouth with a spiral tongue between the palpi.

Class XII. Ryngota. Mouth composed of a beak, or articulated sheath.

Class XIII. Antliata. Mouth composed of a sucker.

The first of these classes contains the order *Coleoptera;* the second, the orders *Orthoptera, Dermaptera,* and *Dictyoptera;* the third, the orders *Thysanura, Trichoptera,* and a part of the *Neuroptera;* the fourth, the order *Hymenoptera;* the fifth, the *Neuroptera;* the sixth, the class *Myriapoda;* the seventh, the class *Arachnoïda;* the eighth, ninth, and tenth, the class *Crustacea;* the eleventh, the order *Lepidoptera;* the twelfth, the orders *Hemiptera* and *Omoptera;* the thirteenth, the order *Diptera.* This system was followed by a very few entomologists, and is now entirely set aside.

In the same year, Clairville published an excellent work on the insects of Switzerland, entitled, "Entomologie Helvetique," in which he has distributed them into the following orders: viz.

I. Peterophora. With wings.
A. Mandibulata. With jaws.
Section 1. *Elythroptera.* Wings crustâceous.
——— 2. *Deratoptera.* Wings coriaceous.
——— 3. *Dictyoptera.* Wings reticulated.
——— 4. *Phleboptera.* Wings veined.
B. Haustellata. With a sucker.
Section 5. *Halteriptera.* Wings with a balance.
——— 6. *Lepidoptera.* Wings covered with powder.
——— 7. *Hemimeroptera.* Wings half obscure, half diaphanous.
II. Aptera. Without wings.
A. Haustellata. With a sucker.
Section 8. *Rophoteira.* With a sharp rostrum.
B. Mandibulata. With jaws.
Section 9. *Pododonera.* Runners.

This first volume treats of the *Curculionidæ,* and is illustrated by some very beautiful plates. Volume second appeared in 1806, and contains the *Carabidæ* and *Dyticidæ.* Both are highly interesting, and are very necessary to the library of an European Entomologist.

"Verzeichniss der Käfer Preussens, &c. von J. K. W. Illiger, Halle, 1798." 8vo. This highly interesting work contains the most accurate descriptions of the Prussian insects, and should find a place in every entomological library.

"Philosophie Entomologique, &c. pour servir d'introduction à la Connoissance des Insectes, &c. par J. F. Saint-Amans, &c. Agen, an. vii." 8vo. It contains descriptions of the parts which compose an insect, and terminates with an exposition of the methodical distribution of Insects by Geoffroy and Linné, combined with that of Fabricius.

"Lepidoptera Pedimontana illustrata a Leonardo de Prunner. Augusta Taurinorum." 8vo.

"Naturgeschichte der schädlichen Nadelholz-Insecten, nebst Anweisung zu ihrer Vertilgung, &c. von G. G. Zinke, Weimer." 8vo.

Voigt, in this very fertile year, published his "Magazin für den neuesten Zustand der Naturkunde mit Büschricht auf die dazu gehörigen Hülfwissenschaften, von J. H. Voigt. Weimer." 8vo.

Schrank also published his "Fauna Boica, &c. Nurnberg." 8vo.

And, in the same year, Paykull published his "Fauna Suecica, Insecta, Upsaliæ," in three octavo volumes.

"M. C. G. Lehmann de Sensibus externis Animalium exsanguinium Insectorum scilicet ac Vermium, &c. Gottingæ." 4to.

"Faunæ Ingricæ Prodromus, exhibens Methodicam descriptionem Insectorum agri Petropolensis, &c. auctore J. Cederheilm, Leipsiæ."

E. Donovan, this year, published in London, "Natural History of the Insects of China," which was the first work that has appeared on the insects of that vast empire. The materials composing this volume (which is in quarto), and from which it was in a great manner formed, were obtained from the first and most authentic sources, including many of the species collected at the time of the embassy of Lord Macartney. This work is illustrated with fifty copperplates, beautifully executed.

In the fourth volume of the "Linnean Transactions," we find, "An Essay on the Eye-like Spot in the Wings of the Locustæ of Fabricius, as indicating the male sex, by Professor A. A. H. Lichtenstein."—"Account and figure of a minute Ichneumon, by G. Shaw, M. D."—"*Amophila,* a new genus of Hymenopterous Insects, including the *Sphex sabulosa* of Linné, by the Reverend W. Kirby."—"Farther observations on the *Wheat Insect,* &c. by T. Marsham, Esq."—"History of Tipula Tritici, and *Ichneumon Tipulæ,* &c. by the Reverend W. Kirby."—"Observations on the genus Pausus, and descriptions of a new species, by A. Afzelius, M. D."

The "Journal de Physique for 1798" (Vols. III. and IV.) contains, 1. "Observations sur les Œstres, par B. Clark."—"Sur les Araignées tendeuses, communiquée par P——;" and Vol. LI. for 1799 (An. IV.) contains, "Exposition d'une Méthode Naturelle pour la Classification des Insectes, par le Citoien Duméril."

Few other works appeared in this year. Amongst them are,

"Entomologische Versuche von C. Crutzer. Wien, 1799." 8vo.

"Europäischen Fauna oder Naturgeschichte der Europäischen Thiere. Von J. A. E. Goeze. Kæfer, Leipzic." 8vo.

"Natural History of the Slug-worm. By W. D. Peck. Boston." 8vo.

"Mémoires pour servir à commencer l'histoire des Araignées Aquatiques. Par J. F. A. O."

In 1800, Cuvier, with the assistance of Duméril, published, in Paris, his "Leçons d'Anatomie Comparée," in which the anatomy of Insects is treated of at great length, and a new systematic arrangement is proposed, in which Insects are divided into those with jaws, such as *Grathaptères, Neuroptères, Hymenoptères, Coleoptères,* and *Othoptères;* and, secondly, into those that want jaws, *Hemiptères, Lepidoptères, Diptères,* and *Aptères.*

"Nouvelle Classification des Mouches a deux ailes, &c. par J. G. Meigen. Paris." 8vo. This is the first production of a man who has enriched the classification of Diptera, not only by describing new species, but by laying the groundwork for their classification. He has in this work characterized eighty-eight genera, and, at the end of each, has enumerated the species. Many of the names proposed nave been since changed by Illiger.

“ Icones Cimicum descriptionibus illustratæ. Dec. 1. Auctore J. F. Wolff. Erlangæ.” 4to. The second fascicule appeared in 1801.

“ Cimicum in Helvetiæ aquis et terris degentium genus in familias redactum, &c. a J. R. Schellenberg. Turici.” 8vo. This tract is illustrated by figures of the genera.

“ G. Payhull, Fauna Suecica. Insecta. Tom. III. Upsaliæ.” 8vo.

“ Natursystem der Ungeflügelten Insekten, von J. F. W. Herbst. Viertes Heft. Berlin.” 4to. This number contains a monograph on Scorpio, with coloured figures.

E. Donovan published in this year his “ Insects of India,” embracing in a general, yet scientific view, a comprehensive display of the most rare and beautiful insects peculiar to these fertile regions.

“ Archiv für Zoologie und Zootomie. Von C. R. W. Wiedmann. Berlin und Braunschweig.” In four volumes 8vo.

“ Verzeichniss meiner Insecten Samlung oder Entomologisches Handbuch für Liebhaber und Samler. Von. J. Sturm, Erst Heft. Nurnberg.” 8vo.

Thunberg produced his “ Museum Naturalium Academiæ Upsalensis,” &c. 4to.

Lastly, the fifth volume of the “ Bibliotheca Hist. Nat. Banksiana,” by J. Dryander, containing several very valuable and numerous references to the works of Entomological writers.

Lamarck, in 1801, published his celebrated “ Systéme des Animaux sans Vertébres,” in which we find considerable advances in Entomological arrangement. The greater portion of the Linnean *Aptera* he has placed in the classes *Crustacea,* and his new class *Arachnides.* The Insecta he divides into, I. With mandibles and maxillæ, Order 1. *Coleoptères;* 2. *Orthoptères;* 3. *Neuroptères.* II. With mandibles and trunk, Order 4. *Hymenoptères.* III. With a trunk or sucker; no mandibles; Order 5. *Lepidoptères;* 6. *Hemiptères;* 7. *Diptères;* 8. *Aptères.*

“ J. C. Fabricii Systema Eleutheratorum, &c. Kiliæ.” Two volumes 8vo.

“ Natursystem aller bekannter inund auländischen Insecten, &c. Von J. F. W. Herbst. Der Käfer neunter Theil. Berlin.”

“ Beiträge zur Insectenhunde, &c. Von A. W. Knoch. Erster Theil. Leipzig.” In this work the author has described with the greatest accuracy several new genera and species of Insects, which are illustrated by some excellent coloured figures.

“ D. Lehmann de Antennis Insectorum.”

“ F. Weberi Observationes Entomologicæ, &c. Kiliæ.” 8vo.

“ Illustratio Iconographica Insectorum, &c. Auctore A. J. Coquebert. Tab. Decas II. Parisiis. An. x.” 4to.

“ Systematisches Verzeichniss, von der Schmetterlingen, &c. Von Lehrern. Zweiter Band. Braunschweig.” 8vo.

“ Kleiner Beytrag zur Entomologie, &c. Von P. Frost. Erster Heft. Erlangen.” 8vo.

“ Der Gesellschaft Naturforschender Freunde zu Berlin. Dritten Band, Berlin,” for this year, contains, “ Zu einer neuen gattung Sceliphon. Darch Herrn Dr Klug.”

“ Sesiæ Europæ, &c. Auctore J. H. Laspeyres. Berolini.” This work is illustrated by some very neat figures of the species.

Illiger's Magazin for this year contains, 1. “ Nachtrag und Berichtigungen zum Verzeichnisse der Käfer Peussens.” 2. “ Namen der Insehten-gattungen.”

“ J. Sturm's Abbildungen zu Karl Illiger's Ueberfetzung. Von Olivier's Entomologie, &c. Narberg.” 4to.

“ Magazin für Insektenkunde, von K. Illiger. Ersten Bandes. Braunschweig.” 8vo. Containing, 1. “ Nachtrag und Berichtigungen zum Verzeichnisse der Käfer Preussens.” 2. “ Ist es richtiger, genus durch Geslecht oder durch Gattung auszudrukken ?” 4. “ Namen der Insekten-Gattungen, ihr Genitiv, ihr grammatisches Geschlecht,” &c. 5. “ Die Deutschen Namen der Insektengattungen.” 6. “ Neue Insekten.” 7. “ Ueber der Winteraufenthalt der Käfer, vom H. Schmid.” 8. “ Bemerkungen über *Lygæus apterus,* von F. Hausmann.” The same work, for 1802, contains, 11. “ Ueber das Fabricische System,” &c. 12. “ Aufzahlung der Käfergattungen nach der Zahl der Trussglieder.” 13. “ Zusatze, Berichtigungen und Bemerkungen zu Fabricii Systema Eleuteratorum.” 14. “ Beiträge zu den Materialien einer künftingen Bearbeitung der Gattung Blattläuse, von F. Hausmann.” 15. “ Bemerkungen über die Europäischen Arten der vierzehnten Familie der Schmetterlinge im 10ten Bande von Herbst's Natursystem, &c. Von J. C. Grafen von Hoffmansegg.” 16. “ Beschreibung eines neuen Werkzengs zum Insectenfange. Von T. Koy ” 17. “ Vorschlag eines neuen auf den Rippenverlauf der flügen gebauten System, von J. D. E. Preyssler.”

We are happy in having it in our power to announce the only purely scientific work on Entomology that has appeared in Britain since the time of Ray. It was published in 1802, by the Rev. W. Kirby, in two volumes octavo, entitled, “ Monographia apum Angliæ;” a Dissertation on the Bees of England. The author commences with an introduction, in which he gives a general view of the rise and progress of this branch of entomology, with remarks on the various works treating of the subject, definitions of the terms used in describing the genera and species by different authors; and, after pointing out the confusion that had reigned throughout the order Hymenoptera, proposes a new set of terms, with comments on terminology in general. The characters of the order Hymenoptera, with the generic characters, &c. are next given, intermixed with remarks on the economy of each group. Under the head “ Addenda,” we have some good remarks on other Hymenopterous genera; and at the end of the first volume, a series of outline plates, explaining the various parts of the mouth, &c. peculiar to each subdivision. The second volume treats of the species, with occasional remarks on the peculiar economy of each. The descriptions are minute, and extremely accurate. It is a fact worth relating, that Latreille, the first of Entomologists, at the same time wrote on the subject, and established similar divisions with those proposed by Kirby, considering each, however, as a peculiar genus. Kirby formed from the Linnean genus Apis two genera, *Apis* and *Melitta*, which answer to Latreille's two families, APIARIÆ and ANDRENETÆ. Latreille's divisions are more numerous and more correct than those of Kirby; but this arose no doubt from the longer experience of the author, and the greater extent of his collection.

" Faune Parisienne (Insectes)," &c. par C. A. Walckenaër. Tom. 1. 8vo. In this work the system of Fabricius is adopted.

" Observationes Entomologicæ, &c. Auctore C. F. Fallén. Lundæ."

" Entomologische Beytrage, Von J. R. Schellenberg. Winterthur." 4to.

" Icones Cimicum. Fas. 3. Auctore J. F. Wolff. Erlangæ." 4to.

" Histoire Naturelle des Fourmis, et recueil de Mémoires et des Observations sur les Abeilles, les Araignées, les Faucheurs et les Autres Insectes." Par P. A. Latreille. Avec figures. Paris, An. x. 8vo. This admirable work is worthy the particular attention of scientific Entomologists.

" Concordance Systématique, servant de table de matières à l'ouvrage de Réaumur, intitule; Mémoires pour servir à l'histoire des Insectes. Par J. N. Vallot." Paris, An. x. 4to.

" Kleiner Beitrag zur Entomologie in einem Verzeichnisse," &c. Von P. Frost. Erstes Heft. Erlangen.

" Coleoptera Microptera Brunsvicentia, &c. distribuit Dr J. L. C. Gravenhorst. Brunsvigæ, 8vo. A most excellent monograph in the genera and species of the genus Staphylinus of Linné.

The " Journal de Physique" for this year contains " Histoire d'un Insecte ou d'un Crustacée," par B. Prevost. This treats of the genus *Branchipus*, incorrectly named *Branchiopoda*.

The sixth volume of the " Transactions of the Linnean Society of London" contains the following entomological papers: 1. " A Dissertation on two Natural Genera hitherto confounded under the name of Mantis." By A. A. H. Lichtenstein. In this paper, *Phasma* is first distinguished from *Mantis*. 2. " Observations on Aphides, to show that they are the principal causes of blight in plants, and the sole cause of the honey-dew. By W. Curtis. 3. " Observations on the Curculio Trifolii." By W. Marwick, Esq. 4. " Farther Remarks on the same," by M. C. G. Lehmann. 5. " Descriptions of some singular Coleopterous Insects." By C. Schreibers. 6. " Observations on several species of the genus Apis, known by the name of *Humble Bees*." By P. Huber. This last paper is extremely valuable, and will be duly noticed, along with the others, in our article INSECTA.

In this year, Mr C. Stewart published anonymously, in Edinburgh, a valuable little work, entitled " Elements of Natural History," the best that has appeared in our language. The greater portion of the second volume is devoted to Entomology. We are sorry to add, that a new edition has lately appeared, in which the author has not availed himself of the important improvements the science has acquired, since the publication of his first edition.

" Observationes Entomologicæ. Pars I. Auctore A. Rönbeck. Lundæ, 1802." 4to.

Mr T. Marsham produced, in the same year, his " Entomologia Britannica," in 1 vol. 8vo; and although it is the worst work (considering the vast advancement of the science at the time) that we have seen, yet, as there was no other on the subject, it has most materially excited the study of Entomology in Great Britain.

The " Annales du Museum d'Histoire Naturelle" was commenced this year, and contains a paper by Latreille, entitled " Observations sur quelques Guepes, et description d'une larve et d'une espèce inédite de Casside." The second volume, which appeared in the year 1803, contains " Dissertation critique sur les espéces d'Ecrevisses connues des Anciens, et sur les noms qu'ils leur ont donnés; par G. Cuvier."

" De Animalium exsanguinium Respiratione. Auctore J. F. L. Hausmann. Hannoveræ, 1803." 4to.

" J. C. Fabricii Systema Ryngotorum, &c. Brunsvigæ, 1803." 8vo. Containing descriptions of the species of the orders Hemiptera and Omoptera.

" Genres des Mouches Diptères représentés en xlii. Planches projettées et dessinées par M. J. R. Schellenberg, et expliquées par deux amateurs de l'Entomologie. Zuric. 1803."

" Monographia Siricum Germaniæ atque generum illis annumeratorum Auctore D. F. Klug, cum tabulis æreis coloratis 8. Berolini, 1803." 4to. This work contains observations on the genera Oryssus and Sirex, with descriptions of the species.

" Vorschlag zu einer neuen in die Classe der Glossaten einzufuhrenden Gattung Platypteryx von J. H. Laspeyres. Berlin, 1803." 4to.

" Index Alphabeticus in J. C. Fabricii Systema Eleatheraterum genera et species continens. Helmstadii, 1803." 4to.

" Der Gesallchaft Naturforschender Freunde zu Berlin. Vierter Band. Berlin, 1803." Contains, 1. " Herrn S. Laspeyres, Vorslag zu einer neuen in die Klasse der Glossaten einzufuhrenden Gattung." 2. " Herr Prediger Herbst, Beschreibung einiger höchstseltener Heuschrecken."

" Versuche über die Insecten. Ein Beitrag zur Verbreitung der Nützlichen und Wissenswürdigen aus der Insectenkunde von C. A. Schmid Ester Theil. Gotha, 1803."

" Entomologische Hefte, &c. Frankfort am Main. 1803," 8vo. This work was conducted by Dr J. J. Hoffmann, Dr J. D. W. Knoch, P. W. J. Müller, and J. M. Linz. It contains several admirable monographs, on Hister, Haltica, and Dorcatoma, which are illustrated with coloured figures very neatly executed.

" Magazin für Insectenkunde, herausgegeben von

Karl Illiger. Zweiter Band. Braunschweig." Contains, " 1. Vertheidigung der Fabrichschen Systems, von J. C. Fabricius." 2. " Nachcrift der Herausgebers zu vorstehenden Aufratze." 3. " Etwas über Gattung, Gattungskennzeichen und Gattungsbenunnung von J. C. G. Karsten." 4. " J. H. Laspeyres Kritische Revision der neuen Ausgabe der Systematischen Verzeichnisses von der Schmetterlingen der Wienergegende." 5. " Auseinandersetzung von zwei unter dem namen *Runica* bischer verweichsalten Tagfalter Arten. *P. Runica* und *P. Medesicate.*" 6. " Verzeichniss der in Portugall einheimische Käfer Erste Leiferung." 7. " J. W. Meigen's Verseuch einer neuen Gattungs-Eintheilung der Europaïschen Zweiflügligen Insecten." 8. " Literatur." 9. " Vermischte Nachrichen und Bemerkungen."

A. H. Haworth published the first part of an elaborate work, entitled Lepidoptera Britannica, the object of which was to give descriptions of the various species of that beautiful order which inhabit Britain. The task was a very difficult one, and the author has, in our opinion, acquitted himself with considerable credit. Two other parts have since appeared, but the work is still incomplete, one part still remaining unpublished.

" Voyage en Hongrie, &c. par R. Townson. Traduit de l'Anglais par Cantwell. Tom. 3. Paris, 1803." 8vo. The original appeared in 1797.

" D. J. F. Blumenbach's Handbuch der Naturgeschite. Gottingen." 8vo. The seventh edition. A French translation appeared at Mentz during the same year.

Lastly, in the third Volume of the Annales du Musuem, two papers by Latreille. 1. Observations sur l'Abeille parietine, &c. et Considerations sur le genre auquelle se rapporte: 2. Des Langoustes du Museum National d'Histoire Naturelle.

J. C. Fabricius published, in 1804, his " Systema Piezatorum, &c. Brunsvigæ."

And J. W. Meigen his celebrated " Klassificazion und Beschreibung der Europaischen Zweiflügligen Insecten (Diptera, *Linné*). Braunschweig. Ester Band." 4to.

" Archiv für die Systematiche Naturgeschite herausgegeben von Dr F. Weber, und Dr D. M. H. Mohr. Ersten Bandes, Erstes Stükk. Leipzig. 1804."

" Icones Cimicum. Fasc. IV. Auctore J. F. Wolff. Erlangæ, 1804." 4to.

James Sowerby published the first number of his " British Miscellany," in 8vo. The few insects figured are highly interesting, but the work, from want of a liberal support, was never continued beyond 12 or 15 numbers.

The seventh volume of the " Transactions of the Linnean Society of London" appeared this year, in which is a paper by William Roxburgh, M. D. on " The Tussech and Arrindy Silkworms of Bengal," which the author informs us produce the Phalæna Mylitta *Drury* ii. T. V. f. 1; and the P. Cynthia *Drury* ii. T. VI. f. 2.

The " Dictionnaire des Sciences Naturelles, par plusieurs Professeurs du Muséum, &c." commenced. The entomological part by Professor Duméril.

The Journal de Physique for the year contains " Essai sur l'Entomologie médicale, par Chaumaton."

" Illustrationes Insectorum Iconographica, &c. Auctore A. J. Coquebert. Tab. Dec. III. Parisiis, An. x. (1804)." 4to. In it are published figures of the species described by Fabricius, from the Parisian cabinets.

" Notice des Abeilles proprement dits; par Latreille." *Annal. du Mus.* Tom. IV.

" Natursystem aller bekannter in-und Ausländischen Insecten. Von. J. F. W. Herbst. Der Schmetterlinge mit 30 illumen. Berlin, 1804." 4to.

Illiger's Magazin for this year contains, " 1. Familien, Gattungen, und Horden der Kafer, *Coleoptera,* von P. A. Latreille: 2. Namenweiser der Familien und Gattungen in Latreille's System der Käfer: 3. Zusätge, Berichtigungen und Bemerkungen zu Fabricii Systema Eleuteratorum. Tom. 1.: 4. Alphabetisches Verzeichniss zu J. Hübner's Abbildungen der Papilionem mit biegefägten Synonymen von J. C. Grafen von Hoffmansegg: 5. Essbare Insecten und eine neue art vom Spinnen: 6. Neuere Insectenwerke: 7. Vorschlag einer neuen Tödtungsmethode der Insecten von M. J. Böhm, und Vertilgung der Borkkäfers, *Ptinus Far,* von Malinowsky: 8. Vermischte Bemerkungen." The same work for 1805 contains the following highly interesting papers: " 1. J. H. Laspeyres Kritishe Revision der neuen Ausgabe des Systematischen Verzeichnisses von der Schmetterlingen der Wiemergegend: 11. Theil: 2. Zuoätze, Berichtigungen und Bemerkungen zu Fabricii Systema Eleuteratorum, Tom. II: 3. Beiträge zur Naturgeschite des Halbdehigen Leuchtkafers, *Lampyris hempitera,* Tab. von P. W. J. Muller: 4. Bemerkungen uber die Fussgliederzahl einiger Käfergattungen in Bezichung auf Illiger's Abhandlung uber diesen Gegenstand in dem Magazin fur Insectenkunde. I. B. p. 185. von P. W. J. Muller: 5. Die Hauschrekkenzüge in mittäglichen Africa. Auszüge ans Barrow's Reise in der Kolonien auf den Vorgeberg der Gattung Hoffnung."

A very interesting work on the various animals that produce a phosphorescent appearance in the sea was published this year. It contains figures of seven new minute species of Edriophthalmous Malacostraca. The book is entitled, " Phosphorescentia maris quatuordecim Lacentium Animalculorum novis speciebus illustrata a Dominico Viviani, &c. cum Tabulis æreis quinque. Genuæ, 1805." 4to.

" Tableau des Aranéides, &c. par C. A. Walckanaër. Paris, 1805." 8vo. This work comprehends the characters of the genera belonging to the natural family Araneidæ, with excellent observations on the parts comprising the mouths, &c. of this interesting group.

" Kritische Revision der Insectenfaune Deutchlands, nach der System bearbeited von Dr G. W. F. Panzer. I.—xcvi. Heft 1. Bandchen. Nürmberg, 1805." 12mo.

" J. C. Fabricii Systema Antliatorum, &c. Brunvigæ, 1805." 8vo.

" G. A. Goldfuss Enumeratio Insectorum Eleutheratorum Capitis Bonæ Spei totiusque Africæ, cum tabula ærea. Erlangæ, 1805." 8vo. Eight new species are described and figured.

"Fauna Austriæ, oder Beschreibung der österreichischen Insecten, &c. Von G. Duftschmid. Ester Theil. Linz und Leipzig. 1805." 8vo.

"Deutschlands Insecten. Von. J. Sturm. 1. Bändchen. Kafer. Nüremberg, 1805. mit 20 Kupfertapeln." 8vo.

"Insectes recuilles en Afrique et en Amerique, &c. par Palisot de Beauvois. Paris." fol.

E. Donovan gave to the world another work on exotic insects, in quarto, entitled, "An Epitome of the Insects of New Holland, New Zealand, &c." This publication is extremely valuable, the figures generally very correct, and the work is rare, few copies having been published.

Lastly, "Vollständige Naturgeschite der Schädlichen Forstinsecten, &c. Von J. M. Bechsteine und G. L. Scharfenberg, mit 13 Quartkupfern. Leipzig." 4to.

In 1806, C. Duméril published his "Zoologie Analytique, ou Méthode Naturelle de Classification des Animaux, &c. Paris." 8vo. In which the *Insecta* and *Arachnoïda* are classed together. All the genera are given in tables, in a clear point of view.

P. A. Latreille produced the first volume of his "Genera Crustaceorum et Insectorum. Paris." 8vo. Two more volumes appeared during the following year, and a fourth in 1809. This is by far the best systematic work hitherto published; but as, in our article INSECTA, we shall follow the general outline of his system, it will be unnecessary to say more on the subject in this place.

Dr G. W. F. Panzer published a tract on Hymenoptera, entitled "Entomologischer Versuch die Jürineschen Gattungen de Linneschen Hymenoptera nach dem Fabriciusschen System zü Prüffin, &c. Nürmberg." 8vo.

"Handbuch der Neuesten Entdeckungen in der Hielmittellehre, von K. F. Burdach. Leipzig." 8vo.

"Svensk Entomologi ab C. Iser. Linköping." 8vo.

"Svensk Zoologi, eller Svenska Djurens Historia, börjad ad C. Quesnal, forstatt ab O. Swartz, utgifver med illuminerande figurer ab J. W. Palmsturch. Stockholm." 8vo.

"Die Schmetterling Sachens, &c. Von F. Ochsenheimer. Erst. Th. Leipzig. 1806." 8vo.

"Entomologie Helvetique, &c. Tom. II. Zurich, 1806." 8vo. This volume treats of the Carabidæ and Dyticidæ.

"Monographia Coleopterum Micropterum, auctore J. L. C. Gravenhorst. Gottingæ, 1806." 8vo.

"Natursystem aller befannter in und Ausländischen Insecten, &c. Von J. F. W. Herbst. Berlin, 1806." 8vo.

The seventh volume of the "Annales du Museum d'Histoire Naturelle" contains, 1. A Memoire by Drandebart de Férrussac fils, on two new species of Entomostraca and Hydrachna: 2. An excellent Dissertation on the Argulus foliaceus, the whole history of which is admirably detailed: 3. A paper by Lepellitier, on several new species of the family Chrysididæ, with good remarks on the group in general, accompanied with figures.

Illiger's Magazin, too, contains some highly interesting papers: 1. "Züsäge zur Terminologie der Insekten:" 2. "W. Kirby's Famien der beinenarten Insekten mit Zuzärzen, Naturweisungen und Bemerkungen:" 3. "Ester Nachtrag zu des Graffen von Hoffmansegg Alphabetischen Verzeichnisse von Hubner's Papilionem. Durch denselben." 4. "Beschreibung der um Odenbach in Departement vom Donnerberg blobrachten Schlammkäfer, Limnius *Illiger*, von P. W. J. Muller." 5. "Beschreibung einer neuen käferguttung: Macronychus, mit der Beschreibung einer neuen art von Parnus, von P. W. J. Müller." 6. "Nachtrag zu der Zusärtzen, Bemerkungen und Berichtigungen zu Fabricii Systema Cleuteratorum:" 7. "Mittel gegon die Blattlause."—The same work for 1807 contains, 1. A paper on 160 species of Heltica: 2. A paper on Portuguese Insects; and, 3. what is by far the most interesting of all, An analysis of Fabricius Systema Glossatorum, as far down as Sphinx.

L. Jurine published his "Nouvelle méthode de Classer les Hymenoptères et les Diptères. Avec figures. Tom. I. Hymenopteres. Geneve. 1807." 4to. An analysis was published in the Journal de Physique of the same year. The author has proposed to arrange into genera the two orders mentioned in his title, solely from the wing-bones, a method by no means new, having been before proposed by Moses Harris, and adopted, to a certain extent, by after writers.

The first part of the "Transactions of the Entomological Society of London" was published this year, and contains notices of several insects not before observed in Great Britain.

An elegant work on the finer exotic Butterflies appeared, entitled "Coloured Specimens, to illustrate the Natural History of Butterflies, from the collection of Mr Lee of Hammersmith." This publication is illustrated by twenty copperplates, so admirably coloured as to resemble highly-finished drawings.

"Observationes Entomologiæ. Pars II. auctore D. Danielsson, Lundæ, 1807." 4to.

"Observationes Entomologiæ. Pars III. auctore P. N. Block, Lundæ, 1807." 4to.

"Monographia Cantharidum et Malachiorum Sueciæ, auctore J. E. Arrhenius, Lundæ, 1807."

"Monographia Cimicum Sueciæ, auctore C. F. Fallén, Hafniæ, 1807." 8vo.

"Deutschlands Fauna, &c. Von J. Sturm. V. Ubtheilung. Die Insecten. Zweites Bändchen. Kafer. Mit 32 Kupfertafeln. Nürmberg, 1807." 12mo.

"Die Schmetterlinge von Europa. Von F. Ochsenheimer. Est. Band. Leipzic, 1807." 8vo.

In the "Nouveau Bulletin des Sciences, par le Société Philomatique de Paris, Tom. I. 1807." 4to. are the following good papers: 1. "Mémoire sur les Mœurs de Ceratina albilabris, *Latr.* par M. Spinola." 2. "Note sur quelques habitudes des Abeilles-bourdons, par A. de Petit-Thouars."

The tenth volume of the "Annales du Museum" contains, "Memoire sur les Mœurs de Ceratina albilabris. Par M. Spinola."

The "Gesellschaft Naturforschender Freunde zu Berlin, 1807," contains, 1. "Arten von Krebsen, von Schneider." 2. "Anatomie der Darmkanals und der Geschlechtstheile vom Carabus monilis, vom Dr Ramdohr.” 3. “ Uber das Leuchten der Fulgorem, als Nachtrag zur vorhergehender Abhandlung, von Graf Hoffmansegg.” 4. “ Uber die Geschechtverschiedenheit der Piezaten, vom Dr F. Klug.” 5. “ Monographie der Elateren mit leuchtenden Flecken auf dem Halsschilde, von K. Illiger.” 6. “ Oxæa, eine neue gattung aus der Ordnung der Piezaten, von F. Klug.” 7. “ Species Apiarum Familiæ novas descripsit, &c. F. Klug.” 8. “ Ein neuer Merkwürdiger Henops, beschrieben, von F. Klug.” The same work for 1808 contains, 1. “ Ueber die Geschlechtsverschiedenheit der Piezater, von D. F. Klug.” 2. “ Ueber die Gattung Cypris *Müller*, vom F. A. Ramdohr.” 3. “ Beytrag zur Naturgeschichte der Vespa Crabro, von Malinowsky.” 4. “ Tinea sociella und colonella, die beiden Geschlechter einer Art, von S. Laspeyres.” 5. “ Die Blattwespen nach ihren Gottungen und Arten Zusammengestellt, vom F. Klug.” This last paper has since been followed up by several others on the same subject; they contain most accurate descriptions of all the species of Terthedo *Linné*, that have been hitherto discovered.

The second part of Schönher's “ Synonomia Insectorum” came out this year; and a very interesting work on the Insects of Sweden, “ Insecta Suecica descripta a L. Gyllenhall,” Tom. I.; comprehending the most detailed descriptions of the Coleoptera that we have yet seen.

The ninth volume of the “ Transactions of the Linnean Society of London” contains, 1. An excellent “ Monograph on the Genus Apion, by the Rev. W. Kirby.” 2. “ Some observations on the Wheat Insect, supposed to be the Wire-worm, by T. Walford, Esq. with notes by T. Marsham, Esq.” 3. “ Descriptions of *notoclea*, a new genus of Coleopterous Insects, from New Holland, by T. Marsham, Esq.” This genus had long before been established by Olivier, under the name *Paropsis*.

“ Die Schmetterlinge von Europa. Von F. Ochsenheimer. Est. Band.” 8vo.

The “ Annales du Museum, Tom. XI.” contains “ Notice biograph. sur J. C. Fabricius. Par Latreille.” And Vol. XII. of the same work, for 1809, contains, 1. “ Nouvelles observations sur le manière dont plusieurs insectes de l'order hyménoptères pourvoient à la subsistance de leur posterité; par Latreille.” This memoir consists of some very interesting observations on the economy of the genera Bembex, Philanthus, Anthophora, and Parnopes. 2. “ Comparison des organes de la mastication des Orthoptères, avec ces des autres animaux; par Marcel de Serres.” The learned author of this paper details the variations presented in the teeth of the mandibles, and at the same time points out the functions he believes them to be destined to perform, in omnivorous, graniverous, and carnivorous orthoptera. He says, that the carnivorous have only the canine teeth; the herbivorous genera have incisors and grinders, and the omnivorous have canine and grinders, but that the latter are smaller, and the former less pointed than in the carnivorous and herbivorous genera. 3. “ Mémoire sur les Métamorphoses du grand Hydrophile,” par M. Miger.

“ Essai sur l'Entomologie du Département du Puy-de-dome. Par J. B. L. Monographie des Lamelli-antennes. Clermont, 1809.” 8vo.

The “ Der Gesellschaft Naturforschender Freunde zu Berlin,” 1809, contains, “ Bemerkungen über die Lebenverhältnisse der Coccinellen überhaupt, und der Coccinella hieroglyphica, *Fabr.* insbesonder vom P. D. Reich.”

The “ Journal de Physique, Tom. LVIII.” of this year, contains, “ Mèmoir sur les yeux composés et les yeux lisses des Orthoptères, &c. par Marcel de Serres.”

“ F. A. Bonelli, Observations Entomologiques, Turin, 1809,” 4to, containing a monograph on the European genera of the Linnean genus Carabus, which he has admirably divided into natural genera, and distributed them into stirpes. It is a complete model for classification.

The “ Berlin Magazine for 1809” contains, “ Bemerkungen über die Sebensverhältnisse de Coccirellem, &c. Von Reich.”

“ G. Bayle Saggio intorno agli Insetti nouvi, &c. Milano, 1809.” 8vo.

The “ Annales du Museum,” Tom. XIII. of the year, contains, 1. “ Latreille sur le genre Anthidium de Fabricius,” &c. in which the species are very well described. 2. “ Jules de Tristan; Mémoire sur quelques crustacés trouvés sur les côtes de Poitou.” In this paper five species of our genera Dynamene, Næsa, and Idotea are described and figured.

In 1810, Latreille published his “ Considerations sur l'Ordre naturelle des Crustacés des Arachnides, et des Insectes.” 8vo. A most excellent little manual for the scientific student.

“ Die Schmetterlinge von Europa. Von F. Ochsenheimer. Ditter. Band.”

“ Specimen Entomologicum Novam Dipteræ deponendi methodum exhibens. Auctore M. Rodhe. Lund. 1810.” 8vo.

In the “ Nouveau Bulletin des Sciences,” we find a paper on a new genus of Diptera, named Nemestrina by Latreille, by Olivier.

“ E. F. Germar, Systematis Glossatorum Prodromus, sistens Bombycum, species secundum oris partium diversitates in nova genera distributosa. Sectio 1. Leipzic, 1810.” 4to. Of this work we shall say more under the article Insecta.

“ Insecta Sucica descripta a Leonardo Gyllenhall, Tom. I. par 2. Scaris, 1810.” This part treats of the Cicindelidæ, Caribidæ, Staphylinidæ, Meloidæ, &c. and is equal to the first part in merit.

The “ Berlin Magazin” contains, 1. “ Einige neue Piezatengattungen, von Dr F. Klug;” and the same work for 1811, 1. “ Ichneumones adciti in genera et familias diversi a Dr Nees ab Esenbeck.”

“ Icones Cimicum. Fas. V. Auctore J. F. Wolff. Erlangæ, 1811.” 4to.

“ G. A Paykull, Monographia Histeroidum. Upsaliæ, 1811. Cum tablis 13. æreis.” 8vo. This is by far the best production of this author. In it he has described and figured all the species he had an opportunity to examine, and has sepatated certain species under the generic title *Hololepta;* he has, however, figured the larva of a Dipterous Insect, for that of his new genus.

The second part of the tenth volume of the " Transactions of the Linnean Society of London" contains, 1. " Descriptions of several new species of Apion, by the Reverend W. Kirby." 2. " Some account of an insect that was taken alive out of a desk that had been made for more than twenty years, by T. Marsham, Esq."

The Annales du Museum, Tom. XVII. et XVIII. contain, 1. " Mémoir anatomique sur un nouvelle espèce du genre Brachinus, par L. Dufour," in which the author shows us the organs by which this genus of Insects prepare and emit the fumes and cause the explosion by which their economy is characterized. This paper is republished in Vol. III. of the Nouveau Bulletin des Sciences for 1812. 2. " De l'Odorat et des Organes qui paroissent en êntre le siége, chez les Orthoptères, par Marcel de Serres;" wherein he combats the generally received opinion that Insects smell by their antennæ or respiratory tracheæ, and seems disposed to think that the Orthoptera probably receive this impression through the medium of the membranaceous points of their palpi.

In the Berlin Magazine for 1811, there is a paper by Nees Von Esenbeck, on the Ichneumones adsciti.

The same work for 1812, Tom. XIX. contains a Mémoire by Latreille, entitled, " Sur un Insecte qui les Anciens réputoient fort venimeux, et qu'ils nommoient Bupreste," in which he attempts to prove the *Buprestis* of the ancients to have been a Meloë, or an insect of the same natural family.

" A. Ahensii, Fauna Insectorum Europæ. Fas. I. Ic. XXV. Halæ. 1812, 12mo."

" Insectes de l'Amérique Equinoctiales, &c. Par Latreille. Seconde Partie. Paris, 1812." fol.

" Fauna Austriæ. Zwenter Thiel. Linz un Leipzig. 1812." 8vo.

" Observationes Entomologiques traduites et extraites d'un ouvrage inédit intitulé. J. N. Vallot, Insectorum incunabula juxta methodicum disposita, &c. Paris, 1812." The Insects are classed according to the plants on which they feed.

" E. F. Germar Systematis Glossatorium prodromus, &c. Sectio II. Leipsiæ, 1812."

" G. R. Treviranus über den Bau der Arachnider. Erlangæ, 1812."

In the fertile year, 1813, were published, " K. A. Ramdohr Abhandlung über die Verdauungswerkzeuge der Insecten, Halle. Mit. 30 Kupfertafern." 4to.

" Insectes de l'Amérique Equinoxiale, Par Latreille. Paris, 1813. Partie II." fol.

" Mémoirs de l'Académie Impériale des Sciences de St Petersbourg, Tom. IV. St Petersbourg, 1813." Contains, 1. " Coleoptera rostrata Capersia, a C. P. Thunberg illustrata."

" E. F. Germar, Resie nach Dalmatien und in das Gebiet von Ragusa. Leipzig, 1813. Mit. Kupfern." 8vo.

" L. Gyllenhal, Insecta Svecica, Tom. I. Pars. 3. 1813." Contains the continuation of the Coleopterous families Bruchidæ, Cusculionidæ, Erotylelidæ, and Chrysomelidæ.

" Specimen novam Hymenoptera disponendi methodum exhibens, &c. Auctoribus C. M. Hellestrom, C. J. Danielson, et C. A. Lundman. Lundæ, 1813." 4to. In this work, the Hymenoptera are distributed into eighteen families, and seventy-one genera, the characters being founded on the form of the antennæ and body, and on the variations in the wing-bones.

The " Noveau Bulletin des Sciences, Tom. III. Paris, 1813," contains, 1. " Essai Historique sur les Crustacées de la mer de Nice; par Risso." 2. " Extrait d'un Mémoire sur le Puceron du Thérébinth, &c. par D'Audebard de Ferrussac." 3. " Extrait d'un Mémoire sur les Araignées; par Lepellitier."

The " Journal de Physique, Tom. LXXVI. 1813," contains, 1. " Extrait d'un Mémoire sur les usages des diverses partes du tube intestinal des Insectes. Par Marcel de Serres." 2. " Rapport fait par Mr Bosc, sur l'ouvrage de Mr Hubert fils, intitule, Recherches sur les Mœurs des Fourmes indigènes."

" Index Entomologicus, sistens omnes Insectorum species, in G. W. Panzeri, Fauna Insectorum Germaniæ descriptas, &c. Pars I. Norimb. 1813." The author, in this index, has availed himself of the observations of Latreille, Borelli, and other celebrated writers.

" Mémoire sur les yeux composés et sur les yeux lisses des Insectes, &c. Par Marcel de Serres. Montpellier, 1813." 8vo. It would be ridiculous to eulogise a man so celebrated as Marcel de Serres. In this work, which is illustrated with beautiful plates, he has shown us that the optic nerve, in Insects with compound eyes, is distributed by separate fibres, one to each fascette, composing the eye itself. And that the simple eyes are supplied, each one, by a peculiar branch of the optic nerve, the branches themselves uniting before they join cervical (or cerebral) ganglion.

" G. J. Billberg, Monographia Mylabridum. Holmæ, 1813. Cum tabulis 7 æreis coloratis." 8vo.

In this year Germar commenced an excellent journal on Entomology, which may be considered as a continuation of Illiger's Magazine. It is entitled, " Magazin der Entomologie. Von Dr E. F. Germar, Halle, 1813." 8vo. It contains, 1. " Naturgeschichte des Carabus gibbus (Zabrus gibbus), eins saatverwüsttenden Insekts. Von Herausgeber." 2. " Insecten in Berstein eingeschlossen, beschrieben; Von Herausgeber." 3. " Bemerkungen über die Sachträger unter der Schmetterlingen ehre Fortpflanzung und Entwiehelung. Von Dr Zinken *gennant* Sömmer."

The first part of Vol. XI. of the " Transactions of the Linnean Society of London" contains, 1. " An Essay on the British species of Meloë, with descriptions of two exotic species, by W. E. Leach." 2. " Strepsiptera, a new order of Insects, &c. By the Reverend W. Kirby." 3. " A Monograph on the British species of Choleva, by W. Spence, Esq."

Vol. XX. of the " Annales de Museum" contains, " Observations sur les diverses parties du Tube intestinal des Insectes. Par Marcel de Serres." In this learned memoir, we find a complete account of the intestinal canal of Insects, which always consists of the œsophagus, the stomach, biliary vessels, and intestines. The last part presents a vast number of modifications. In very voracious Insects, and in those whose masticatory organs are not well developed, a supplementary part may be observed, which is not very unlike the gizzard of birds. After giving an account of the coats that enter into the composition of the canal in its different parts, he informs us, that the length of the œsophagus depends on the form of the thorax. In some instances, it is as long as half of the intestinal canal, and at other times it varies from one to nine or twenty-six. The stomach is likewise variable in its size, according to the functions designed for it to fulfil. The intestines are generally longer in herbiverous Insects, than in those that feed on living bodies. We regret that our space will not allow us to give a detailed analysis of this valuable memoir, to which we refer those of our readers who wish to learn farther particulars.

In 1814 was published, " Précis des Decouvertes Somiologiques ou Zoologiques et Botaniques, par C. S. Rafinesque. Palerme, 1814." 12mo. In this little work, which contains indications of several new genera and species, the Crustacea are termed Plaxolia, and the Insects Entomia.

" Nouvelles Observations sur les Abeilles. (2de edit.) Paris, 1814." 8vo. For an account of this work, see article Bee, Vol. II. p. 212.

" Anthracides Sueciæ, auctore E. H. Berglund. Lundæ, 1814." 4to.

" Hydrocorides et Naucorides Sueciæ, auctore J. G. Liljegren. Lundæ, 1814." 4to.

" Diptera Sueciæ distripta a C. F. Fallen. Tom. I. Lundæ, 1814." 4to.

" Asilici Sueciæ, auetore J. G. Waldenström. Lundæ, 1814." 8vo.

" Specimen novam Hemiptera disponendi methodum exhibens, auctore M. Rodhe. Lundæ, 1814." 4to.

" L'Art Entomologique, Poëme didactique. Par Mr Le Roux. Versailles, 1814." 8vo. This volume, although in Rhyme, is not devoid of merit, and will not prove uninteresting to the entomogist.

" A. Ahensii, Fauna Insectorum Europæ. Fas. 2. ic. 25. cum descriptionibus. Halæ, 1814." 12mo.

" C. L. G. Löwe, de partibus quibus Insecta spiritus ducunt. Disscrtatio inauguralis Med. Halæ, 1814." 8vo.

The " Bulletin des Sciences, 1814," contains 1. " Sur une nouvelle éspece du genre Cymothoa de Fabricius, par Le Sucur." 2. " Observations sur la bouche des Papillons, &c. par J.-C. Savigny."

The " Berlin Magazine for 1814" contains, 1. " Die Körpertheile der Zweiflüglichen Insecten. Ein terminologischer versuch; von P. F. Bouché." 2. " Die Blattwespen, &c." and 3. " Die Europaischen Arten der Insecten gattung Leucospis; von F. Klug." 4. " Ichneumones adsciti in genera et familias divisi, a Nees von Esenbeck."

" The Zoological Miscellany; or Descriptions of New, Rare, or Highly Interesting Animals, by William Elford Leach. Illustrated with Coloured Figures, by R. P. Nodder." Vol. I. This work contains descriptions and figures of several new and curious genera and species of insects. A second volume was published in 1815.

" Empidæ Sueciæ, &c. auctore P. N. Rhodin. Lundæ, 1815." 4to.

" Platypezinæ et Bombyliarii Sueciæ, &c. auctore L. F. Flodin. Lundæ, 1815." 4to.

" C. Spengel, Commentarius de partibus quibus Insecta spiritus ducunt. Accedunt Tab. 3. æri incisæ et pictæ. Lipsiæ, 1815." 4to.

" J. Sturm, Deutschlands Fauna. Drittes Bändchen. Käfer. Nürnberg, 1815." 12mo.

" Monographia Ichneumonum Pedestrium, &c. auctore J. L. C. Gravenhorst. Lipsiæ, 1815."

" H. M. Gaede, Beiträge zür Anatomie der Insekten. Altona, 1815. Mit 2 Kupfertafeln." 4to.

" Dr Herold, Entwickelelungs-Geschichte der Schmetterlinge, Anatomisch und Physiologisch bearbeitet, 1815. Mit 33 Kup." 4to.

The " Mémoires du Muséum d'histoire naturelle, &c. Tom. I." This is a new series of the " Annales du Museum; it contains, " Note sur les Mœurs des Bourdons, par La Billardiere."

The " Mémoirs de l'Académie Imperiale des Sciences de St Pétersbourg, Tom. V. 1815," contains, 1. " Hemipterorum maxillosorum genera, &c. a C. P. Thunberg." 2. " De Cancris Camtschaticis, Oniscis, Entomostracis, et Cancellis marinis microscopicis noctilucentibus, cum appendice de Acaris et Ricinis Camptschaticis, auctore Tilesio."

" Magazin der Entomologie, herausgegeben von Dr E. F. Germar, Halle, 1815," 8vo. contains, 1. " Eenige Erfahrungen und Bemerkungen, von J. F. Kyber." 2. " Abhandlung über die Gattung Anthidium, *Fabr.* von P. A. Latreille." This is extracted from Vol. XIII. of the " Annales du Muséum. 3. " Südamerikanische Insecten gesemmelt, von V. Humboldt und Bonpland, von P. A. Latreille."

The " Berlin Magazine" contains, 1. " Lapton femoralis, eine neue Ichneumonidengattung, &c. Von Nees von Esenbeck." 2. " A continuation of Klug's descriptions of the Tenthredinæ." 3. " Die Gattung Leucosia, *Fabr.* Von P. Lichtenstein.

" An Introduction to Entomology, &c. By W. Kirby and W. Spence. Vol. I. London, 1815." 8vo. This is a popular book, published with a view to excite to the study of Entomology. Vol. II. appeared in 1817. The third volume, we understand, will contain the nomeclature.

" Transactions of the Linnean Society of London," Vol. XI. Part II. contains, 1. " Observations on the Cancer Salinus of Linnæus, by the Rev. T. Racket." 2. " Addendum to the Strepsiptera, by the Rev. W. Kirby." 3. " Further observations on the Meloe, with descriptions of six exotic species, by W. E. Leach." 4. " A tabular view of the external characters of four classes of Animals, which Linné arranged under Insecta; with the distribution of the genera, composing three of the classes into orders, &c. and descriptions of several new genera and species, by W. E. Leach."

In 1816, the most philosophic work that we have seen, was published, entitled, " Mémoires sur les Animaux, sans Vertèbres, par Jules-César Savigny. Premier Partie, 1st Fascicule, Mem 1–2. Théorie des Organes de la bouche des Crustacés et des Insectes. Paris, 1806." 8vo. In this work the author has proved in a most satisfactory manner, that the mouths of all Insects, Crustacea and Myriapoda, are composed of one pair of mandibles, and two pairs of maxillæ; and that the lower lip of Insects is formed by the union of the second pair of maxillæ. In the Myriapoda the lower lip is composed of the two pairs of maxillæ confluent, their mandibles being soldered to it. The two anterior pairs of thoracic legs are, in the same class of animals, converted into auxiliary lower lips, the third pair only assisting them in locomotion, which is performed by the ventral or abdominal legs. The mandibles in Lepidoptera perform no function, they are but rudimentary. The first pair of maxillæ in the same order is prolonged into a spiral tongue, bearing palpi at its base; and the lower lip is composed of the exterior maxillæ united, like that of all other insects. We earnestly recommend this treatise to those occupied with the study of Entomology.

" Empides Sueciæ, auctore N. Kihlgren. Lundæ, 1816." 4to.

" Observations sur le Xenos Vesparum, par M. Jurine."

" Histoire naturelle des Crustacés des Environs de Nice, par A. Risso. Ornée de Graveurcs. Paris, 1816." 8vo. A most valuable work, containing a vast number of observations relating to the economy of these animals.

" Die Schmetterlinge von Europa. Von. F. Ochsenheimer. Bieter Band, 1816."

" Dr H. T. L. Reichenbach Monographia Pselaphorum. Lipsiæ, 1816. Cum tabulis coloratis 2." 8vo.

" Malinousky, Elementarbuch der Insectenkunde, vorzügluh der Käfer. Quedlinburg bei Basse, 1816." 8vo.

Two new editions of the " Nouveau Dictionnaire d'Histoire Naturelle," &c. were commenced this year; the first, entitled, " Dictionnaire des Sciences Naturelles, &c. par plusiers Professeurs du Jardin du Roi," &c. The articles on insects are written by Professor Duméril; those on Crustacea by Dr Leach, correspondent of the French Museum. One volume is published quarterly. The second professes only to be a new edition, and retains the old title. The Entomological articles are written by Latreille. One volume is produced every month. The first volume contains the interesting articles, Abeille, Argule, Araignée, Aile, and Bouche.

The " Journal de Physique, &c. Tom. LXXXII. and LXXXIII.," contain, 1. " Observations sur la filiation des Animaux, depuis le Polype jusqu'au Singe, par De Barbançoise." 2. " Observations pour servir à une classification des Animaux, par le même." 3. " Prodrome d'une nouvelle distribution Systematique des Regne Animal, par H. D. de Blainville;" in which the author has distributed the Linnean Insecta into the following classes. 1. With six legs, Héxapodes (or insects properly so called). 2. With eight legs, Octopodes, (Spiders and Acari). 3. With ten legs, Decapodes (Malacostraca, with pedunculated eyes, excepting Squilla). 4. Legs variable in number, Hétéropodes (Squilla, Branchipus, &c.). 5. Legs fourteen, Tétradécapodes (our sessile eyed Malacostraca). 6. Legs equal in number to the joints of the body (Myriapoda).

The " Bulletin des Sciences," for the year, contains, 1. " Sur une nouvelle distribution des Classes des Crustacés, des Myriapodes et des Arachnides, par W. E. Leach." 2. " Prodrome d'une nouvelle distribution systematique du Règne Animal, par H. de Blainville."

" Synopsis of four new species of Crustacea found in the United States, by C. S. Rafinesque, Esq." This notice is published in the " American Monthly Magazine, Vol. II., New York, 1817." 8vo.

" Insectes de l'Amerique Equinoctiale, &c. par Latreille, Partie 2."

" Synonymia Insectorum, von C. J. Schonherr, Ester Band. Skara, 1817. (Hispa-molorchus)." Also, " Appendix ad C. J. Schönherr, Synonymia Insectorum, Tom. I. Sistens descriptiones novarum specierum."

The " Massachusett's Agricultural Repository and Journal, Vol. IV., Boston, 1817," 8vo., contains a paper by Professor Peck, " On the Natural History of two Insects; the one a Scolytus, the other a Rhynchænus."

" Transactions of the Linnean Society," Vol. XI. Part 1. contains, " On the Classification of the Notonectidæ, by W. E. Leach."

" Journal of the Academy of Natural Sciences of Philadelphia, Vol. I., 1817." 8vo. This volume contains some excellent papers on the Crustacea of the United States, by Thomas Say, Esq. who has studied the subject with great success, and has discovered and described several very interesting new genera and species.

" J. A. C. Sturm, Deutchlands Insecten, Zweites Bändchen. Käfer, mit 32 Kupfertofeln, Nürnberg, 1817." 8vo.

" Mémoires du Museum, &c. Tom. III., 1817," contains, 1. " Introduction à la Géographie générale des Arachnides et des Insectes, ou des Climats propres à ces animaux, par P. A. Latreille." 2. " Considerations nouvelles et generales sur les Insectes vivant en Société, par le même."

" American Entomology, &c. illustrated by coloured figures, by T. Say, Vol. I. No. 1., Philadelphia, 1817." 8vo. This work promises to be of great utility to the science, and to make us acquainted with the but little investigated entomological treasures of North America.

" Magazin der Entomologie, Herausgegeben, von Dr E. F. Germar und Dr J. L. T. F. Zincken *genaunt* Sommer, Halle, 1817." Contains, 1. " Beiträge zur Verwandlurgeschte einiger Käferarten, von J. F. Kyber." 2. " Die Linneischen Tineen in ihre natürlichen Gottungen aufgelöft und beschrieben, von J. L. T. F. Z. g. Sommer." 3. " W. Kirby's Monographie des Gattung Apion *Herbst*, aus dem Englischen übersetzt, mit Bemerkungen und eingeschalteten Beschreibungen neuer arten, von E. F. Germar." This dissertation not only contains the species described by Kirby, but a vast number of new species, which are illustrated by several very neatly coloured figures. 4. " Bemerkungen über einige Insekten, von P. W. J. Müller."

" Le Regne Animal, &c. par M. Le Chevalier

Cuvier, Vol. III., continent, "Les Crustacés, Les Arachnides, et Les Insectes, par M. Latreille." The Crustacea are arranged into five orders, viz. 1. *Decapodes*, comprehending our orders Brachyura and Macroura. 2. *Stomapodes*, including Squilla. 3. *Amphipodes*, embracing our first division of the Edriophthalma, or those with compressed bodies. 4. *Isopodes*, under which he has placed the Onisci of Linné, or our Edriophthalma with depressed bodies. 5. *Branchiopodes*, or the Entomostraca of Müller. The Arachnoïda he divides into two orders. 1. *Pulmones* (Unogata, *Fabr.*). 2. *Trachéennes ;* but the characters have not directed his classification rigorously. The Myriapoda he has placed with the insects, of which they form the first order. To the orders given in his Genera Insectorum, he has added Rhipiptera (Strepsiptera, Kirby), which is placed between the Hymenoptera and the Diptera.

The "Mémoires du Museum, Tom. IV.," contains, "Observations sur les usages du Vaisseau dorsal, &c. par Marcel de Serres."

"The Zoological Miscellany, Vol. III., 1817," contains the following Entomological papers ; 1. "On the characters of Matuta, with descriptions of the species." 2. "Micippa, a new genus of Brachyurous Malacostraca." 3. "Monograph on the genera and species of the genus Leucosia, *Fabr.*" 4. "On the Thalassina of Latreille." 5. "On the genus Atya." 6. "The character of the class Myriapoda, with descriptions of some of the species." 7. "On the character of the class Arachnoida, and of its families. 8. "On the genera of Scorpionidæ, with descriptions of the British species, of chelifer and obisium." 9. "On the Orders of Insects." 10. "On the Genera of Thysanura." 11. "On the genera of Anoplura." 12. "On the genera of Dyticidæ." 13. "On four genera hitherto called Silpha." 14. "On the Histeridæ." 15. "On the Pselaphidæ." 16. "On the Parnidæ." 17. "On Hydrophilidæ and Helophoridæ." 18. "On the genera of Sphæridiadæ." 19. "On the Tenthedinidæ." 20. "On the Rhipiptera of Latreille."

In the "Mémoires de L'Academie Imperial de St Pétersbourg," we find, 1. "Coleoptera Capensia antennis lamellatis, A. C. P. Thunberg." 2. "Decades tres Eleuteratorum novorum descripsit, J. F. Eschocholtz ;" in which five new genera are established.

Vol. I. Part 2. of the "Journal of the Academy of Natural Sciences of Philadephia," contains a continuation of excellent Memoirs on the Crustacea of the United States, by T. Say, Esq.

The "Journal de Physique" (Vols LXXXVI. and LXXXVII.) contains, 1. "Recherches sur la Metamorphose du canal alimentaire chez les Insectes, par M. Dutrochet." 2. "Sur une nouvelle espèce de Tenthrède, par M. Bosc." 3. "Sur quelques genres nouveaux de Crustacés, par M. Leach." 4. "Recherches anatomiques sur les Scolies et sur quelques Insectes Hymenoptères, par Leon Dufour." The same work for 1819, Vol. LXXXVIII., contains, 1. "Sur les Rhipiptères de Latreille, ordres d' Insectes nommés Strepsiptera, par Kirby; par M. Leach." 2. "Description de deux nouvelles espèces de Thynnus, découvertes dans la Nouvelle Hollande, par M. Rob. Brown ; par M. Leach." 3. "Descriptions, par M. Leach, de quelques nouveaux genres et espéces d'animaux découverts en Afrique, par Mr T. E. Bowdich.".

Vol. XII. Part II. of the "Transactions of the Linnean Society" was published in July 1819, although it bears the date 1818. It contains two papers on Insects, by the Reverend W. Kirby; the one is named "a Century of Insects," the other, "Descriptions of several new species of Insects, collected in New Holland by R. Brown, Esq."

"The Entomologist's useful Compendium, &c. by G. Samouelle, London." 8vo. This is a valuable work, and will tend materially to advance the study of British Entomology, since it is arranged after the natural method. It does infinite credit to its ingenious author.

ENTRE-DUERO-E-MINHO, one of the provinces into which the kingdom of Portugal is divided. It is bounded on the north by the river Minho, which divides it from Spain, and on the south by the river Duero. The Atlantic Ocean is its western boundary; and, on the eastern side, a range of lofty mountains separates it from the province of Tras los Montes. It has a much denser population than any other part either of Spain or Portugal. Its extent is 291 square leagues, and in 1798 (the last census) its inhabitants amounted to 907,965.

It enjoys the most fertile soil, the most salubrious climate, and the most beautiful rivulets of any part of the peninsula. Its vegetable productions are wheat, maize, oranges, lemons, figs, and especially wine. The latter is the great object of export, and, indeed, forms the principal trade of the whole kingdom, as almost all the red wine, commonly called port, from the place whence it is shipped, is the produce of this province. There are manufactures of hats, of silks, of linens, of sail-cloth, and of woollens, and though not rendered sufficiently cheap to be exported to the other countries of Europe, they supply the domestic consumption, and furnish exports to Brasil and the settlements on the coast of Africa.

The rivers next in importance to those which form the boundaries are the Lima, the Cabado, and the Ave, all of which, aided by the mountains, form natural defences against an invading enemy. Though Oporto, both in population and wealth, is the first city; yet Braga, as the see of an archbishop, is the capital of this province. (w. w.)

EQUATIONS. As we are accidentally prevented from inserting in its proper place, an original and elaborate view of the theory of EQUATIONS, we shall, for the instruction and gratification of our scientific readers, depart so far from our general plan, as to give the article in the form of an ADDENDUM to this volume.

ERNESTI (JOHN AUGUSTUS), one of the most illustrious Philologers and Theologians of the last century. He was born on 4th August 1707, at Tennstadt, of which place his father, likewise a distinguished theologian, was pastor, and superintendent of the electoral dioceses of Thuringia, Salz, and Sangerhusen. After having received his first instruction in the learned languages, under the domestic discipline of his father, and in the gymnasium of his native town, he was sent at the age of sixteen to the celebrated Saxon cloister school of Pforta. Here he continued four years. At the age of twenty he entered the University of Wittemberg, where he studied eloquence and ancient literature under the celebrated Berger, theology under Wernsdorf, and the Wolfian philosophy under Schlosser. From Wittemberg he passed to the University of Leipsig, where he applied himself to the mathematical sciences under Hausen, following the courses of Boerner and Deyling on theology, and the lectures of Gottsched on German eloquence. In 1730, he was made Master in the Faculty of Philosophy. In the following year he accepted the office of Conrector in the Thoman school of Leipsig, of which J. M. Gesner was then Rector; and on Gesner's vocation, as professor of eloquence, to Göttingen, he succeeded him as Rector. In this situation, by his erudition, diligence, and the elegance of his methods, he surpassed all his contemporaries, and created an epoch in Germany for the study of the ancient authors. From this office, in opposition to the present custom, which precludes a translation into the universities to the masters of the subordinate schools, he was, in 1742, named as Extraordinary Professor of Ancient Literature in the University of Leipsig, and in 1756, promoted to the Ordinary Professorship of Eloquence. In both these chairs he knew how to combine more intellect, philosophy, and taste, than had been done by any of his predecessors. His reputation as a scholar, and his rational treatment of the biblical exegesis, paved the way to his entrance into the Theological Faculty. Through the elegance of his learning, and his manner of discussion, he co-operated with Baumgarten of Halle in disengaging dogmatic theology from the scholastic and mystical excrescences with which it was then deformed; and thereby contributed greatly to the new revolution in theology, although he himself never deviated from the ancient system. In these deserving labours, and with unbroken health, he attained an honourable old age; and died, after a short illness, in his seventy-sixth year, on 11th September 1781.

Whether Ernesti be considered as a philologer or theologian, it is perhaps as much from the impulsion which he gave to sacred and profane criticism in Germany, as from the intrinsic excellence of his own works in either department, that he must derive his reputation. With Gesner, he instituted a new school in ancient literature; and after Crocus, Melancthon, and Camerarius, has been perhaps the greatest reformer and promoter of classical learning in Germany. With Semler he partially co-operated in the great revolution of Lutheran theology; though he is guiltless of all participation in the deductions which many of those who profess themselves his disciples, have drawn from the principles which he established.

An enthusiastic and enlightened study of the ancient Greek and Roman authors is the well-merited boast of the present German literature. This commenced, in its existing form, towards the middle of the last century. Not that Germany, before that period, had neglected ancient literature, or could not enumerate her proportion among the great names of classical erudition. No nation, in fact, had produced so many, or more illustrious scholars immediately after the Reformation; but for a long time polite literature had become deformed, if not neglected, in proportion as religious wars and polemical theology had exhausted and engrossed her governments and universities. The German scholars were chiefly theologians; and theologians who had studied everything in reference to their peculiar profession. Add to this, that the most disgusting and inefficient methods had been introduced; whereby the spirit of the instruction was at utter variance with the object of the study. Accordingly, during the whole of the seventeenth and the first half of the eighteenth century, Germany was far excelled by Holland in the number and excellence of her philologers; and it was not until the appearance of Gesner and Ernesti, with their somewhat earlier contemporaries, Cortius, Daniel Longolius, and Michael Heusinger, that she could oppose above one or two rivals to the great critics of the Dutch schools. Gesner and Ernesti, however, through the influence of their lectures at the greater universities of Göttingen and Leipsig, through the wider extent of their labours in philology, and still more through the greater excellence of their methods, are alone entitled to be held the founders of the new German school of ancient literature. Both excelled their philological countrymen in taste, in the elegance of their Latin style, in a philosophical spirit, and in a wider acquaintance with the subsidiary branches of erudition. Both made an advantageous use of their critical knowledge of the languages; both looked at once to the words and to the subject of the ancient writers; established and applied the rules of a legitimate interpretation; and carefully analysed the meaning as well as the form of the expression. Both contributed effectually to expel the old absurd, and disgusting methods of instruction from the schools and universities, and to introduce an improved and more effectual system. To the epoch which they formed, many circumstances indeed contributed:—their acquaintance with the Dutch criticism; the universal enthusiasm of the Germans for establishing a national literature, and for becoming, at the same time, reformers in the departments of ancient learning; and withal the spirit of philosophy which at that period, in Germany, began more and more to blend itself with every part of science and literature. It is also true that their editions do not possess the complement of erudition and criticism which distinguish those of many of their contemporaries: their commentaries have the precision, but how inferior are they in certainty, copiousness and depth of illustration, to those of the philologers of Holland? In their editions of the Latin classics, they returned back to the somewhat inconvenient method of Cellarius, collecting their principal illustrations into an *Index Rerum et Verborum*, as is done by Gesner in his *Quinctilian*, and by Ernesti in his *Cicero;* not, however, that they did not possess the means of illustrating their author with a rich, critical, and philological commentary; of which the former has given ample proof in his editions of the *Scriptores de Re Rustica*, and in his *Claudian*, the latter in his two most valuable labours, his *Suetonius* and *Tacitus*. Both, but especially Ernesti, have detected grammatical niceties in the Latin tongue, which had escaped all preceding critics; such, among others, are the use of the subjunctive mood after the pronoun *qui*, and the legitimate consecution of the tenses. His canons are, however, not without exceptions. As an editor of the Greek classics, Ernesti deserves hardly to be named beside his Dutch contemporaries Hemsterhuis, Valkenaer, Ruhnken, or his colleague and enemy, the learned and unfortunate Reiske. How insignificant are his own labours in his editions of Homer and Callimachus? In regard to the higher criticism, it was not even attempted by Ernesti. But to him and to Gesner, the peculiar praise is owing, of having formed, partly by their discipline and partly by their example, philologers greater than themselves; and to them is due the honour of having so strongly excited in Germany that enthusiasm for ancient learning, which has now, unfortunately, no parallel in the other countries of Europe.

As a theologian, Ernesti is far less conspicuous than as a scholar, and his influence not so marked either on his contemporaries or on his successors. Before the middle of the eighteenth century, the Spenerian pietism had been almost banished from the Lutheran theology; and the professors of that faculty in the Protestant universities of Germany no longer excluded philosophy from all interference in the doctrine of Christian belief. It had then been boldly proclaimed and maintained with pre-eminent ability by Semler, that Luther had commenced and not finished the Reformation of religion; but that this Reformation must still proceed, and that religion, like other branches of knowledge, must become purer and more perfect, in proportion to the increase of knowledge, and the developement of the human mind. At this date, accordingly, the theologians of Germany had begun to disregard the nonconformity of their doctrines with the Formula of the Lutheran church; and after this period, few were at all apprehensive of openly controverting its tenets, when at variance with the results of their own speculations. From the unrestrained freedom of thought in matters of religion, which was now indulged, if not even encouraged, by the governments in their different universities, every one was at perfect liberty, without any derogation from his character as a clergyman, or instructor, to maintain and promulgate what opinions in religion he chose; and it must be acknowledged, that the theologians have made, and are still making, every use and abuse of this licence, and have arrived at every conclusion that piety and learning, as well as presumption, folly, and irreligion, can suggest. It was at the commencement of this important era that Ernesti flourished as a theologian.

Of the three sciences subsidiary to theology, philosophy, history, and the grammatical exegesis, the first had been imperfectly applied, and without any interesting result, by Baumgarten, a scholar of Wolf; but the second, the historical interpretation, had, in the hands of Semler, been productive of conclusions subversive of much that had been hitherto held orthodox and even sacred. In the grammatical interpretation of the New Testament some imperfect progress had been made by Bengel; but the new epoch in the biblical exegesis commences with John David Michaelis for the Old, and with Ernesti for the New Testament. It is, indeed, chiefly in *hermeneutic* that Ernesti has any claim to the character of a great theologian. But here his merits are distinguished, and, at the period when his *Institutio Interpretis N. T.* was published, almost peculiar to himself. He applied himself to the interpretation of the Sacred Scriptures, after a long and familiar acquaintance with the Greek and Roman writers; and when formed in his mind and taste by a constant study of these patterns. His interpretation of the New Testament bears the character of both these circumstances. It is not only the matter, but, at the same time, the manner, in which it is conveyed; it is the selection of subjects, with the precision, the pregnant brevity, the elegance and simplicity in which they are expressed, that confers on this little book so high and so singular a value. We find in it the principles of a general interpretation, and this without the assistance of any particular philosophy, not even of the Wolfian, to which Ernesti was attached; but consisting of observations and rules, which, though already enunciated, and applied in the criticism of the profane writers, had never rigorously been employed in the biblical exegesis. He admits in the sacred writings only *one acceptation*, and that the *grammatical*, convertible and the same with the *logical* and *historical*. The Scriptures, therefore, having this in common with all other writings, it follows that they can only be explained like mere human compositions; that the rules of interpretation are the same in both; and that only through some peculiar constitution of speech and writing could any possible distinction between these subsist. He therefore justly censures the opinion of those who, in the illustration of the Scriptures, refer every thing to the illumination of the Holy Spirit; as well as that of others who, in contempt of all knowledge of the languages, would explain words by things, and thus introduce into the holy writings their peculiar glosses and opinions. The *analogy of faith*, as a rule of interpretation, he greatly limits; and teaches that it can never alone afford the explanation of words, but only determine the choice among their possible significations, and must always stand in need of philology as an assistant. The spirit of Ernesti's interpretation gives no countenance, however, to the results which many of his followers have deduced from the grammatical and historical exegeses. Every principle of his interpretation rests on the assumed inspiration of the holy books; and there is not perhaps a better antidote to the poisonous tenets of many of those who profess to be of his school, than the diligent study of his *Interpres*, and the relative *Acroases* of Morus. In the higher criticism of the sacred books Ernesti did nothing. In dogmatic he always expressed great contempt of strict systematic theology; and though he lectured for many years on the Aphorisms of Neumann, it was rather in refutation than in support of his text-book.

Among his works the following are the more important:

I. In Profane Literature:

Initia Doctrinæ Solidioris, 1736, 8vo: many subsequent editions. A work not only valuable by reason of the real excellence of the matter, but more particularly deserving an attentive study, on account of the purity of the Latin, in discussing subjects of philosophy known only to the moderns.

Initia Rhetorica, 1730.

Xenophontis Memorabilia Socratis, cum notis, 1737; often reprinted.

Ciceronis Opera cum clave. 1737, 2d Edit. Halæ, 1757, 3d Edit. Ibid. 1776, 8vo, 6 vols.

Suetonius cum Animadversionibus, 1748. 2d Edit. 1775–8.

Taciti Opera cum notis J. Lipsii, Jo. Fr. Gronovii et suis, 1752. 2d Edit. 1772. 8vo. Another edition, with many additions and improvements, has been procured by Oberlin.

Aristophanis Nubes cum Scholiis Antiquis et præfatione. 1754, 8vo.

Corradi Quæstura cum præfatione, 1754. 8vo. See Wyttenbach in his *Vita Ruhnkenii.*

Hederici Lexicon Græcum multis Vocabulorum millibus Auctum. 1754–67. 8vo.

Homeri Opera Omnia, ex Recensione, et cum Notis Sam. Clarkii, accessit Varietas Lectionum MS. Lips. et Edit. Vet. cura J. A. E. qui et suas Notas adspersit. 1759–64. 5 vols. 8vo.

Callimachi Hymni et Epigrammata, cum Notis Var. Latine vertit atque Notis adjecit. Lugd. Bat. 1761. 8vo. 2 vols.

Polybius cum Notis Var. Præfationem et Glossarium Polybianum adjecit. Viennæ et Lips. 1764. 3 vols. 8vo.

Archæologia Litteraria, 1768. A new and improved edition by Martini.

Horatius Tursellinus de Particulis, 1769. 8vo.

Fabricii Bibliotheca Latina nunc melius delecta, rectius digesta et aucta. Vol. I. and II. 1773, Vol. III. 1774, 8vo; unfinished. The learned Professor Beck of Leipsic has recently announced that he is soon to publish a fourth volume to complete the edition.

II. In Sacred Literature:

Antimuratorius sive Confutatio Disputationis Muratorianæ de rebus Liturgicis, 1755–58.

Neue Theologische Bibliothek. Vol. I. to X. 1760–69. 8vo.

Institutio Interpretis Nov. Test. 1761. Reprinted in the same year at Leyden. 2d Edit. 1765. 3d Edit. 1775. 8vo.

Neueste Theologische Bibliothek. Vol. I. to X. 1771–75. 8vo.

Besides these he published above a hundred smaller works in the form of Prefaces, Academical Dissertations, Programmata, Memoriæ, Elogia, Epistles, Orations, Translations, &c. Many of those have been collected in the three following publications: *Opuscula Oratoria.* Lugd. Bat. 1762. 2d Edit. 1767. 8vo. *Opuscula Philologica et Critica.* Lugd. Bat. 1764. 2d Edit. 1776. 8vo. *Opuscula Theologica.* Lips. 1773. 8vo.

ESSEXSHIRE is bounded on the south by the River Thames, on the east by the German Ocean, on the north by the counties of Suffolk and Cambridgeshire, and on the west by Hertfordshire and Middlesex. Its surface contains 1473 square miles, according to the recent measurement of the Board of Ordnance. The population, which, by the census of 1801, amounted to 226,437 inhabitants, had increased in the succeeding ten years to 252,473; which, on 942,720 acres of land, gives nearly one human being to three acres and three quarters; but as the rivers and estuaries form a portion of the county, the inhabitants may be calculated at one to three acres and a-half.

Essex may be considered as a mere agricultural county; for though, from the near approach of one part of it to the metropolis of the kingdom, there are some manufactories established, which find both their raw materials and their consumption in London, and though in one district of the county there are remains of the once extensive manufactories which were brought from Flanders to this island, the number of persons occupied in them bears but a very small proportion to that part of the population which depends on agriculture.

Oyster Fishery.

Although nearly half the county is bounded by the sea, or by navigable rivers, it carries on no foreign commerce, and what vessels belong to it are employed, either in conveying to London the produce of its agriculture, or in the oyster fishery, which occupies a considerable tonnage and many seafaring persons. The oysters are bred in both the rivers Coln and Crouch; in the former they are protected by the seniorial rights of the corporation of Colchester, and in the latter by the proprietor of that river, Sir Henry Mildmay. The spawn is deposited in the months of April and May; and it is said the shell about it begins to form within twenty-four hours. The fishermen are forbidden to dredge for them at this season. In the month of July the dredgers separate the small oysters from the stones on which the spawn was deposited, and on which they have grown, and lay them down in the channels of the river till they grow of a fit size for consumption, which is determined by a gage, kept for that purpose by the water-bailiff of Colchester. The stones or other substances to which the young oysters had adhered, are again thrown into the water from whence they were taken; as they apprehend the accumulation of the ouse at the bottom of the river would otherwise generate such an increase of muscles and cockles as would destroy the breed of oysters. The number of vessels of different sizes employed in this branch of industry, from ten to forty tons burdens, amounts to near three hundred, and the quantity of oysters, varying in different years, which are caught, are from 18,000 to 24,000 bushels. The larger description of vessels are employed, part of the year, on the shores of Hampshire and Dorsetshire in dredging for the native oysters, which are afterwards deposited in the beds of Essex and Kent, to fatten for the London market. The uncertain produce of the breeding grounds in Essex makes it necessary to have recourse to the more distant coasts to obtain the requisite supply.

Distribution of Population.

From being almost wholly an agricultural county, the far greater part of the inhabitants of Essex are found in villages. The principal places with their population, according to the late census, is as follow:

Colchester,	12,544
Chelmsford,	4649
Walthamstow,	3772
Harwich,	3732
Saffron-Walden,	3403
Halsted,	3279
Romford,	3244
Malden,	2679
Bocking,	2544
Coggeshall,	2471
Barking,	2421
Witham,	2352
Braintree,	2298
Waltham Abbey,	2287
Dunmow,	2279

The towns of Thaxted, Harlow, Epping, Dedham, Billericay, Brentwood, Rochford, Manningtree, Burnham, and Greys, contain each from 1000 to 2000 inhabitants.

Manufactures.

The woollen manufactures are confined to Colchester, Bocking, Halsted, and Coggeshall. The Flemings originally introduced the art of making woollen cloths into this country, and it soon spread from hence, first to the districts nearer to parts producing the wool, and more recently to those where fuel is most abundant. What remains now is principally the manufacture of baizes, some of which are sent to Devonshire, where they are spotted, finished, and exported; but the greater portion is a kind made of the long wool of Lincolnshire, very stout, shaggy, and broad, known by the name of South Sea baize. These are sent to London white, and are there dyed to some of the most expensive colours, so that the cost of dyeing and finishing frequently amounts to more than the price of the baize. They are generally exported to Spanish America, formerly through the peninsula, but recently direct, and they form the clothing of the inhabitants of the cold regions of the Andes. A kind of stuff called Says is likewise made here, which, like the baize, is commonly dyed and finished in London, and is exported to Spain and Italy, where it is adopted for the dress of the clergy.

The manufactures are, however, rapidly declining, and will probably, in a few years, become extinct. The improvements in machinery, the fine streams of water for turning mills, and the low price of fuel, have created a competition in the northern counties with which it is not possible that Essex can long contend. On the eastern side of the county, contiguous to London, there are some establishments for printing calicoes and for bleaching. There are also manufactories of sal-ammoniac, of Prussian blue, of iron liquor for the calico printers, and some other chemical preparations.

Forests.

The face of the county is generally very beautiful; it is well inclosed; for the most part displays good verdant pastures; the hills, none of which rise to great heights, are cultivated to the tops, and there are abundance of trees, especially oak and chesnut, which give a rich appearance to the prospects. There is no county in England in which the proportion of waste land is so small. The forests and wastes can indeed scarcely be considered as utterly uncultivated, and the whole of them do not amount to more than 14,000 acres, including the two forests of Epping and Hainault. These belong to the crown; though the inhabitants of many surrounding parishes have the right of pasturage for their cattle upon them. The king has an unlimited right to keep deer on all the inclosed woods, and the occupiers of land, in the various parishes included within the ancient boundaries of the forests, have a right to feed horses and cows, but no other cattle. The numerous common rights have led to considerable devastation of the timber of these forests, and considerable injury to the property of the crown, but plans have been lately adopted for preserving the trees, and converting a part into a nursery for growing timber for the royal navy. The vicinity to navigation makes these forests well deserving to be appropriated to this purpose.

Soil and Culture.

That part of Essex which lies on the banks of the Thames, and on the shores of the ocean, is a rich alluvial soil on a subsoil of very tenacious clay. It produces, with good cultivation, most abundant crops of wheat, beans, oats, and clover. It is found necessary on the cultivation to fallow very frequently, and repeated ploughings is a practice very generally adopted. The swing-plough is much used, and sometimes a wheel-plough drawn by two, and occasionally by three, horses a-breast, which are guided with long reins by the ploughman. In fallowing it is common to plough the land six or seven times, and it is not unusual with the best cultivators to plough it eight or even ten times. After the summer fallow, by which the soil becomes completely pulverized, and rendered as fine as a garden, it is sometimes the practice to sow wheat in the autumn, but it is more common to let it remain through the winter; and then, after a spring ploughing, to sow barley or oats. The rotation of crops which usually succeeds to a fallow is, 1. Barley or oats; 2. Clover, red or white, mostly the former; 3. Wheat; 4. Beans, twice hoed at least; 5. Wheat. After this course the land is again fallowed. The whole produce of the course of crops is said to depend on the accuracy and skill exercised in the process of fallowing.

There is in this district some land adapted for turnips, and the rotation on such soils is usually, 1. Turnips; 2. Oats or barley; 3. Clover; 4. Wheat; 5. Beans; 6. Wheat. These courses are occasionally varied, tares being introduced when the clover fails, and sometimes pease being substituted for beans. The best cultivators often omit the second crop of wheat, and fallow again after the beans. A rotation which is sanctioned by some very skilful agriculturists is the following: 1. Fallow; 2. Barley or oats; 3. Clover; 4. Beans; 5. Wheat; 6. Tares or pease; 7. Wheat. In this case the manure is laid on the clover ley for the bean crop. In the district we are describing all the farms have a portion more or less extensive of rich marsh land, on which oxen are fed, which supplies hay for winter consumption, and is consequently the source from whence the manure is derived. The best wheat that is brought to the market of the metropolis is raised in the part of Essex of which we are speaking, which is usually denominated the *hundreds*. It has the convenience of water-carriage to London; the rent of land is comparatively low, and it is of extraordinary fertility; but it suffers from a scarcity of good water. It is, especially in the autumn, a very agueish country; and though, of late, the roads have been much improved, they are still in such a state as, added to its insalubrity, prevents the gentry from residing on their estates.

The middle part of Essex rises above the level of the marshy lands, but partakes, in a considerable degree, of their unhealthiness. Around the town of Colchester, for a considerable distance, the soil is a dry loam, well calculated for turnips, and then the most general system adopted is the four course husbandry of Norfolk, viz. turnip, barley, clover, and wheat. A variation is, in some instances, introduced by taking a crop of pease after the wheat, and occasionally tares are sown after the barley instead of clover, as that latter plant will sometimes fail, if too frequently repeated. The greater part of the district is, however, of a clayey loam, on a subsoil of clay, and too tenacious for the turnip system. Much of this is good old pasture land, used solely for feeding, and to which the plough is never applied. The arable land is highly productive; the crops of wheat and beans especially are very luxuriant, and their produce of the best quality. The practice of fallowing is pursued as in the district before described, but so many ploughings are not deemed to be necessary. The rotation is various, but it rarely occurs that wheat is sown immediately after the fallow. Most commonly the succession is, 1. Fallow; 2. Barley; 3. Beans; 4. Wheat; 5. Tares; 6. Barley; 7. Clover. When the land is more wet, which, in spite of excellent draining, is frequently the case, the rotation is, 1. Fallow; 2. Oats; 3. Clover; 4. Wheat. When manure is abundant the heavy soils are cropped in the following rotation with great success: 1. Fallow; 2. Beans; 3. Wheat; 4. Tares; 5. Barley; 6. Clover; 7. Beans; 8. Wheat. In this rotation, the clearing the ground from weeds depends on the use of the hoe, which is applied most carefully to the crops of beans.

The western part of the county, especially where it borders on Hertfordshire, is, in general, land of a very inferior quality, and, without most expensive cultivation, yields but light crops. One extensive district, called the Rodings, still practises a most singular system of husbandry, known now in Essex only, though formerly it was adopted on poor lands in some other counties. It is, 1. A year's fallow, 2. Wheat, 3. Fallow, 4. Barley, and then repeat the same course; thus having one-half the arable land constantly without any crop. The soil is a tenacious clay, of a reddish colour, upon a subsoil of white clay. It is difficult to pulverize, and, with wet, potches so much as not to admit of ploughing when the atmosphere is moist. There are but small parts of this district which produces clover, pease, tares, or beans, and what hay is grown is confined to the narrow borders of the rivulets which run in the valleys.

In the south-western part of the county, the agriculture assumes that system which is adapted to the supply of the wants of the metropolis. A great portion of the land is in permanent pasture, or grows hay to furnish the markets of Smithfield and Whitechapel. The arable land is generally cultivated with a rotation of three crops, viz. potatoes, wheat, and clover; and, as London supplies abundance of manure, by applying it very liberally to the young clover, after the wheat is harvested, such culture produces most abundant crops, and the land is cleaned by the potatoe culture. In this kind of husbandry, which, indeed, can only be conducted where manure is to be obtained with great facility, the plough is only used once in the rotation, after the clover; as the potatoes are planted, and the digging them up sufficiently prepares the land for wheat.

Cattle.

Essex feeds some sheep, but very few are bred in the county. Calves are suckled to a great extent, and the rearing them to furnish veal for the London market is the principal dependence of many farmers. The whiteness of the veal is produced by a great attention to cleanliness, by regular periods of suckling, and by giving them a small portion of barley-meal mixed with chalk. The tendency to fatten is promoted by administering narcotic drugs, which keep the young animals in a quiescent state. Though the county affords such abundance of excellent pasture, yet the fattening of calves is so much more profitable than the dairy, that it is supplied with butter from other counties. Epping has indeed been celebrated for its excellent butter; but the greater part of what is sold in London under that denomination is the produce of Northamptonshire, Buckinghamshire, and other counties. London is supplied with much of its beef from Essex. The bullocks, in a lean state, are brought from Scotland, from Wales, and some from Devonshire, and are fattened in this county, sometimes on the rich, natural meadows, sometimes on turnips, with the addition of oil-cake.

Several other agricultural productions are cultivated in Essex. Hops are grown near Chelmsford, and in a few other districts. Saffron is cultivated near Saffron Walden with great success. Mustard is an advantageous crop in the islands of Foulness and Wallasea, and on the embanked marshes. On some rich old pasture land, when first broken up, three crops are raised together, viz. carraway seed, coriander seed, and teasels, for the baize manufacturers. The three kinds of seed are sowed together, in the spring of the year. The harvest of the coriander takes place in the following autumn. The carraway is a biennial plant, and the is fit to be gathered in July of the succeed- and, in September of the same year, the are cut. The carraway sometimes produces a crop a second, or even a third year. This cultivation is deemed an excellent preparation for the growth of wheat, on lands which are so prolific as to require some degree of exhaustion; as, in the process of this treble cropping, the hoe is very liberally applied, it keeps the ground free from weeds. There are few counties in England, taking the whole of them together, in which the agriculture is so skilfully conducted, or where the productiveness is so great.

Size of Estates.

The landed property in Essex, as in other counties near to the metropolis, is very much divided; there are no overgrown estates, though some of considerable value, belonging to a few individuals; but the greater part is in moderate-sized farms, which can be easily disposed of, and which are frequently purchased from the savings of the commercial class in London.

Rivers.

The only good harbour in this county is Harwich, whence the packets for Holland are dispatched, and where there is a royal dock-yard, in which some frigates are built and repaired. The river Coln is navigable for small vessels to Colchester, and the Blackwater river to Walden. The Crouch is navigable for the largest ships, but passing through an unhealthy country, and having few inhabitants on its borders, it is useless to the purposes of commerce. The river Lea is navigable by barges a distance of 25 miles. There are no canals in this county, but one is projected, to unite the river Lea with the Cam, and thus create internal navigation from Lynn to London.

The seats of noblemen and gentlemen in this county are very numerous, especially on the western side of it, where it approaches to the metropolis, and where many of the richer citizens have fixed their country residences. The most remarkable are, Audley End, belonging to Lord Braybrooke; Braxted Lodge, Peter Duncane, Esq.; Copped Hall, John Conyers, Esq.; Dagenham Park, Sir Thomas Neave; Easter Lodge, Viscount Maynard; Felix Hall, Charles Western; Gosfield Hall, Marquis of Buckingham; Hallingbury Place, John Houblon, Esq.; Hill Hall, Sir William Smith; Langlees, William Tuffnell, Esq.; Mistley Hall, F. H. Rigby, Esq.; Moulsham Hall, Sir H. C. St John Mildmay; Roydon, Sir George Duckett; Terling Place, John Strutt, Esq.; Thorndon Hall, Lord Petre; Wansted

House, Hon. William Pole Tylney Long Wellesley; Weald Hall, Christopher Towers, Esq.; Bell House, Sir Thomas Lennard; Whitley, Thomas Walford, Esq. The family of Capel derive the title of Earl from this county, that of Nassau from the town of Rochford; and Mr Abbot late Speaker of the House of Commons, has been created Lord Colchester.

(w. w.)

EUROPE,

Comparative Advantages and Disadvantages of this Division of the Globe.

One of the great divisions of the globe. On a first view, Europe appears to be less favoured by nature than the other quarters of the globe over which it has obtained so great an ascendancy. It is much smaller in extent; its rocky and mountainous surface does not admit of those noble rivers, like inland seas, which lay open the remotest regions of Asia and America to the commerce of the world. Its vegetable productions are neither so various nor so exuberant; and it is poorly supplied with the precious metals, and with many of those commodities on which mankind set the greatest value. On the other hand, the climate of Europe, if it nourishes a less luxuriant vegetation, is of an equal and temperate kind, well adapted to preserve the human frame in that state of health and vigour which fits it for labour, and promotes the developement of the intellectual and moral powers. The mountains that intersect its surface were barriers which enabled infant communities to protect themselves from violence, and to lay the foundation of arts, knowledge, and civilization. If it has few large navigable rivers, its inland seas and bays are the finest in the world, and were the means of creating and nourishing that commercial spirit which has been one great source of its improvement. Though comparatively deficient in gold and silver, it is abundantly supplied with those useful metals and minerals which minister still more essentially to the wants of civilized life. Its apparent defects have become the source of real benefits, and the foundation of its grandeur. The disadvantages of its soil and climate have excited the industry of its inhabitants, given them clearer ideas of property, kindled a resolute spirit to defend their rights, and called into existence that skill and enterprise, and those innumerable arts and inventions, which have enabled the inhabitants of this apparently barren and rocky promontory to command the riches and luxuries of all the most favoured regions of the globe. It is only in Europe that knowledge and the arts seem to be indigenous. Though they have appeared at times among some of the nations of Asia, they have either stopt short after advancing a few steps, or they have speedily retrograded and perished, like something foreign to the genius of the people. In Europe, on the contrary, they have sprung up at distant periods, and in a variety of situations; they have risen spontaneously and rapidly, and declined slowly; and when they disappeared, it was evident, they were but crushed for the time by external violence, to rise again when the pressure had subsided. It is only in Europe, and among colonies of Europeans, that the powers of the human mind, breaking through the slavish attachment to ancient usages and institutions, have developed that principle of progressive improvement of which it is impossible to calculate the final results. The rudest tribe in Europe, in which this principle has taken root, has a certain source of superiority over the most improved nations of Asia and Africa, where society remains perfectly stationary. If these nations are ever destined to advance in civilization, they must borrow from Europe those arts which she has invented, and which belong to civilized life in every climate. But the tenacious adherence of rude nations to the customs and superstitions of their ancestors will not allow us to hope that the benefits of civilization will be rapidly diffused in this way. It is more probable, that colonies from the older states of Europe will multiply, as the population becomes more and more redundant; and that these colonies will carry the arts and knowledge, the language and manners of Europe with them, to the other quarters of the world. From prejudices on both sides, it is found that two races in very different stages of civilization do not readily amalgamate; and it is therefore probable, that the feebler inhabitants of these countries, like the American Indians, will be gradually displaced by the continued encroachments of the more energetic race of Europe. Such a change, however, must take place slowly, and there is nothing in it to alarm humanity. The vast number of tribes that people Asia and Africa seem born only to be the victims of savage superstition and ferocious tyranny. No treatment they are likely to experience from European colonies can render their condition worse; and were the whole swarm of these nations to die out in the course of nature without being renewed, no great deduction would be made from the sum of human enjoyment. Should the state of things we have been contemplating, and which seems to arise naturally out of the circumstances of Europe, and the other quarters of the globe, be realized, it will be curious to reflect on the circle of changes which will then be completed. The ancient inhabitants of Europe, as well as the modern, were originally colonies sent off from the surplus population of Asia. Here they have thrown off their barbarism, invented and improved arts and sciences, and carried their social institutions to a high degree of perfection; and now, in the maturity of their strength, they are throwing back their surplus numbers upon Asia, to conquer and supplant the remains of those tribes from whom they originally sprung.

Boundaries and Extent.

Europe is bounded on the north and west by the Arctic and Atlantic Oceans; on the south by the

Mediterranean; on the east by the rivers Don, Wolga, and Kama, and by the Uralian Mountains from the Kama to the Arctic Ocean. These are the limits most generally admitted. Some alterations have been proposed on the south-east side, with the view of making the boundary line correspond more accurately with the physical divisions of the earth's surface; but as they have not obtained the sanction of geographers generally, the line that is best known seems entitled to the preference. The greatest length of the Continent of Europe is from Cape St Vincent to the Sea of Kara, in the direction of north-east and south-west, and is 3490 English miles. Its greatest extent from north to south is from Cape Matapan to Cape North, 2420 miles. Its greatest extent from east to west is on the parallel of 48°, from Brest to River Don, 2230 miles. The superfices of Europe, including the Azores, Iceland, Nova Zembla, and all the other islands belonging to it, is 3,432,000 English square miles.

Climate. The climate of Europe is distinguished by two peculiarities. It enjoys a higher mean temperature than any of the other great divisions of the world, in the corresponding latitudes; and it is not subject to such violent extremes of heat and cold. These advantages it owes chiefly to its numerous seas, inland bays, and lakes, which render its temperature similar to that of islands; and partly also, according to Humboldt, to its situation at the western extremity of the greatest range of dry land on the surface of the globe; the western sides of all continents being warmer than the eastern. Europe lies almost entirely within the temperate zone, not more than one-fourteenth part of its surface being within the arctic circle. Only a very small part of it is uninhabitable from cold, and it nowhere suffers much from excessive heat. The mean temperature at its southern extremity, in the latitude of 36°, is about 66° of Fahrenheit; and at Cape North in the latitude of 71°, where the mean temperature is 32°, the cold is not greater than in the latitudes of 55 or 56 on the east coasts of Asia and America. Hence Europe is habitable at a higher latitude by 12 or 14 degrees than either of these continents. The following table, taken from Humboldt's *Memoir on the Distribution of Heat* (abridged in Dr Thomson's *Annals of Philosophy*, XI. 188), shows the difference in temperature between Europe and the eastern shores of Asia and America at the parallel of 40°: the difference is much greater at the parallel of 60°.

	Lat.	Mean Temperature of the Year.	of 3 Winter Months.	of 3 Summer Months.

Pekin, .	39.54	55.2	26.8	82.6
New York,	40.40	53.8	29.8	79.2

There is a difference of the same kind between the temperature of the sea-coasts of Europe and the interior. In islands, and on the sea-coast, the mean temperature of the year is higher, and the heat is more equally distributed through the different seasons. As we advance from the coast eastward the mean annual temperature diminishes, but the heat of summer and the cold of winter increase. Thus London has the same mean annual temperature as Vienna, but it has the summer of Petersburgh, and the winter is warmer than at Milan. The Mediterranean, the Baltic, and inland lakes, produce the same effect as the ocean in an inferior degree. The two following tables are taken from Humboldt (*Annals of Phil.* XI. 188); the first shows the temperature of the year, and the various seasons in places having the same latitude; the second shows the different distribution of heat through the various seasons in places having the same mean annual temperature.

Mountains. The mountains of Europe are more numerous in proportion to its extent than those of the other great continents, but they are of less elevation than the mountains of America and Asia. The highest, and the most extensive chains in Europe, run generally in the direction of east and west, and are placed near its southern shores. The central mass of the Alps, with which all the other mountains in the south of Europe are connected, forms the summit of the continent, and determines the position of the surface, and the course of most of the rivers. From this central point the surface of the land descends to the sea by a series of valleys, skirted by subordinate chains. The three countries to the southward of the Alps and their branches, Greece, Italy, and Spain, consist of mountainous peninsulas projecting into the Mediterranean. The countries to the west, north, and east of the Alps, which present more extensive plains and gentle declivities, are the seats of the three principal monarchies in the south of Europe. Austria, seated on the eastern declivity, rules over the countries watered by the Danube; France occupies the western declivity, and the countries watered by the principal streams that flow to the west; and Prussia the countries watered by the streams that flow to the north. If we descend from the Alps to the sea in a western direction, the first valley we meet with is the level part of Switzerland between the Alps and Mount Jura, elevated from 1600 to 1800 feet above the sea; the second, between Jura and the Cevennes, some hundred feet lower; and the third, and lowest, extends from the Cevennes to

---

Copenhagen is about 620 miles east from Edinburgh; Moscow about 1000 miles farther.

the Atlantic. In a north and north-east direction, the first valley is Bavaria, the second Bohemia, both of which are completely enclosed by mountains; the third, consisting of Silesia, Brandenburg, and Poland, terminates in the Baltic. In an eastern direction the first valley is Austria, the second, Hungary, both encircled with mountains; the third, Bulgaria, extends to the Black Sea. South from the Alps we have first the valley of Lombardy, and then the narrow coast of Genoa. The vast plain occupied by Russia, and the eastern part of the Swedish peninsula, may be considered as a prolongation of the valley of Prussia and Poland, extending to the Dofrines on the west, the Uralians on the east, and Mount Caucasus on the south. Thus, in a general point of view, the elevation and declivity of the large plains of southern Europe bear a certain relation to the position and distance of the central mass of the Alps.

Alps. The principal mass of the Alps extends in a semicircle from Nice, on the shores of the Mediterranean, to Trieste, on the Adriatic, a distance of 550 miles. Southward of Mont Blanc, the Alps consist of a single chain, with many lateral branches, which lie chiefly on the west side; but immediately to the eastward of Mont Blanc, the principal chain divides into two, which enclose the sources of the Rhone. These meet, again, at St Gothard, and, on the east side of it, part into three chains, one of which loses itself in Bavaria, another in Austria near Vienna, and the third terminates near Trieste. A lateral chain, of no great elevation, passes eastward, and connects the Alps with the mountains of European Turkey. Smaller branches connect the Alps with the Bohemian and Carpathian mountains on the north, with the Vosges and Cevennes on the west, and, through the latter, with the Pyrenees. The Apennines are but a prolongation of the Alps on the south. Mont Blanc, the loftiest of the Alps, and the highest mountain in Europe, has an elevation of 15,680 English feet; and Mount Rosa, the Jungfrau, the Schreikhorn, and several other summits, approach to this height. The elevation of the chain diminishes towards both extremities. In general, the escarpments, or steepest sides, are turned towards Italy, and the lateral and subordinate branches are most numerous, and extend farthest on the opposite side. The central chain of the Alps consists chiefly of granite, gneiss, sienite, and other primitive rocks. Among the lateral ridges, to the westward of St Gothard, calcareous rocks, with clay-slate and mica-slate, abound on the side of France; on the side of Italy, the ridges are narrower, magnesian rocks abound, and the clay-slate is wanting. On both sides are found great deposits of gravel, and large detached blocks or boulders, often at a vast distance from their original situations. Eastward from St Gothard, the central chain is accompanied on each side by a calcareous chain of great elevation.* Though the summits of the Alps are steep and rocky, and the higher vallies are filled with glaciers, there is much good soil below. The vine grows to the height of 1600 feet above the sea, the oak to the height of 3390, corn to 4200 feet, and the larch to 6720 feet. At 6400 feet above the sea, we have the climate of Lapland, in latitude 68°, so that a degree of latitude, in the northern half of the temperate zone in Europe, corresponds to an elevation of about 290 feet. The inferior limit of perpetual snow, according to Humboldt, is at the height of 8760 feet, in the latitude of 46°. (*Annals of Phil.* II. 373.)

Pyrenees. The chain of the Pyrenees, which is next to the Alps in elevation, runs in the direction of east and west. Its length is about 240 miles; but if we include the Cantabrian mountains, which continue in the same line without interruption, the whole length will be about 500 miles. The central chain of the proper Pyrenees is of granite, but the most elevated summits are of secondary limestone, and lie on the south side of the granite. Mont Perdu, esteemed the loftiest of the whole range, consists of fetid limestone, and rises to the height of 11,270 feet. The south side of the Pyrenees is rugged and precipitous; but, on the north, there is a gradual descent to the plains of France by a series of parallel ridges diminishing in height. The Cantabrian mountains are lower than the Pyrenees, and present their steepest sides to the north. There are four other chains of mountains in Spain, all running in a direction approaching to east and west, and all connected with one another and with the Pyrenees. The most elevated of these is the Sierra Nevada, the southmost, one of whose summits rises to the height of 11,660 feet. (Laborde, I. 173.) The inferior limit of perpetual snow on the Pyrenees is at the height of 8960. The red pine rises to the height of 7480 feet, which is about 700 feet higher than any species of trees on the Alps.†

Apennines. The Apennines form an uninterrupted chain 750 miles in length, extending from the south-west termination of the Alps near Nice to the Straits of Messina. The north-west division, which skirts the basin of Lombardy, consists chiefly of greywacké; from Tuscany to near the southern extremity, the prevailing rock is secondary limestone. Granite and other primitive rocks are found at the two extremities in Liguria and Calabria, but are wholly wanting in the intermediate space. The most considerable elevations are about the middle of the chain, where Il Gransasso rises to the height of 9570 feet. (*Edinb. Review*, XXVI. 156.)

Carpathians. The Carpathian and Sudetic mountains, with the Erzegebirge and Boehmerwald, may be considered as forming one continued chain, the length of which, from the point where it strikes the Danube in Hungary, to the point where it strikes the same river in Bavaria, is about 1200 miles, exclusive of the transverse branches which separate Moravia from Bohemia and Hungary. The declivities of this long range of mountains are steepest on the south side. The elevations are lowest on the west, and generally increase as we advance eastward, till we [illegible] to the sources of the Thiess in the north of Hungary after which they again decline. The Fi at the westmost point of the chain, is 4030 feet high; Schnekoppe, the highest of the Sudetic mountains, is 5280 feet, and Lomnitz in Hungary, the loftiest of the whole range, is 8460 feet. None of these mountains rise to the region of perpetual snow, the inferior limit of which, according to Wahlenberg, is about 60 feet above the summit of Lomnitz. The most elevated parts of these mountains consist of primitive rocks; corn and fruit trees are said to grow at a greater height upon the Carpathians than upon the Alps, though the latter are two degrees farther south.*

---

* Mentelle et Malte-Brun, *Geographie*, Paris, 1803–5, VII. 509.

† Mentelle et Malte-Brun, *Geog.* XV. 52.—*Annals of Phil.* VII. 373.

Dofrines. The chain of the Dofrines, or great Scandinavian Alps, is about 1000 miles in length, and has a general elevation of from 6000 to 6500 feet. The altitude of Snahatta, near the centre of the chain, in latitude 63, is about 8120 feet. (Von Buch's *Travels*.) These mountains consist almost entirely of primitive rocks, and present their steepest sides to the west. On Sulitelma, the highest mountain of this chain in Lapland, in latitude 67.10, the inferior limit of perpetual snow is at the height of 3500 feet.

Urals. The Uralian mountains, which form the boundary of Europe on the north-east, are but imperfectly known. Some of their summits are covered with perpetual snow, but their height is believed not to exceed that of the Scandinavian Alps. They consist chiefly of primitive rocks. The whole length of the chain, which runs nearly north and south, is about 1400 miles, but more than one-half of it is in Asia.

Mountains of Turkey. Of the mountains of European Turkey, we know as little as of the Urals. From a central point, nearly equidistant from the Danube, the Adriatic, and the Ægean Sea, three chains proceed in different directions; one, the ancient Hemus, runs eastward to the Black Sea; a second, north-westward, till it joins the Carnic Alps; and a third, southward through the peninsula of Greece. These principal chains send out many branches, but neither their height, nor their geological structure, is known with any degree of accuracy.

Cevennes. The Cevennes in the south of France extend about 300 miles in length from north to south, and their two most elevated summits, Mont d'Or and Cantal, rise to the height of 6400 and 6100 feet. Mount Jura, between France and Switzerland, has nearly the same elevation. The Vosges, a small chain in the north-east of France, rise nowhere more than 4600 feet above the sea. (Mentelle et Malte-Brun, *Geog.* XVI. 6, 29, 44.)

Mountains of Britain. The mountains of Britain extend with some interruptions over a space of 530 miles, along the west side of the island. They are not placed in chains, but rather in irregular groups, and consist chiefly of primitive and transition rocks. Snowden in Caernarvonshire, the highest mountain in Wales, has an elevation of 3568 feet. Bennevis in Inverness-shire, which rises 4350 feet above the sea, is the highest land in the island. (Jameson's *Geography*, 319, 320.)

Volcanoes. There are thirteen volcanoes in Europe, which all situated in the vicinity of the sea. The most remarkable are, Mount Etna, in Sicily, which is 10,963 feet in height. (Jameson.) Its eruptions happen very irregularly; sometimes 50 or 100 years have intervened between one eruption and another, at other times less than one year. Mount Vesuvius, in Naples, which lies about 200 miles north from Etna, is 3900 feet high. (Jameson.) Its eruptions are less frequent than those of Etna. Stromboli, which occupies an island in the Mediterranean, about 80 miles north from Etna, is the only volcano in Europe that throws out smoke or flames constantly. Heckla is a mountain near the south coast of Iceland, 4900 feet high. (Jameson.) Its eruptions are not frequent. The last was in 1783.

Rivers. Europe is well watered with rivers, but they are but brooks compared with the mighty streams of Asia and America; and, from the unevenness of the surface, afford, in general, no great extent of inland navigation. The Danube, the largest river that is entirely in Europe, is about 1500 miles in length, and waters a superficies of 370,000 square miles. But the Amazons, though only twice the length of the Danube, waters a surface seven times as large, and equal to four-fifths of the Continent of Europe; and, as the quantity of rain that falls in tropical countries is much greater than in northern latitudes, it is probable, notwithstanding the increased evaporation there, that the Amazons conveys more water than all the rivers of Europe put together. If we divide the length of the Danube into a hundred parts, the length of the principal rivers of Europe, expressed in these parts, will be as follows:

Danube,	100
Wolga (partly in Asia),	130
Dneiper,	72
Don,	69
Rhine,	49
Elbe,	42
Vistula,	41
Loire,	37
Tagus,	32
Oder,	31
Rhone,	30
Seine,	23
Po,	21
Tiber,	10
Thames,	9

A much smaller proportion of the waters of the European Continent flows into the Mediterranean than the extent of its coasts would lead us to expect. The high mountains that range along the south of Europe, parallel to its shores, from Gibraltar to Constantinople, turn the course of the large streams in an opposite direction. Though the length of the line of coast between the points last-mentioned, without computing minute sinuosities, is 4000 miles, or one-fourth of the circumference of Europe, not more than one-tenth of the waters of this quarter of the globe fall into the Mediterranean. The Black Sea, on the other hand, which presents only 850 miles of coast on the side of Europe, receives one-fourth of its waters. It will be seen, from the subjoined table, that one-tenth part of the waters of Europe flow into Asia by the Wolga; that the Black Sea and the Baltic alone receive one-half, while only about one-sixth falls into the Atlantic. If the whole of the river waters of Europe be divided into a hundred parts, their distribution will be nearly as follows:

---

* Mentelle et Malte-Brun, V. 8. XVI. 62.—Wahlenberg, in *Annals of Phil.* IX. 140.

	Length of Coast in Miles.	Water conveyed by Rivers in parts.

The Caspian Sea (in Asia),		10

(*Arrowsmith's Atlas.*)

We are not acquainted with the height of the sources of many of the European rivers above the sea. Those of the Danube, according to Malte-Brun, are from 2100 to 2200 English feet, which gives a fall of one foot and a half *per* mile; but, near the sea, the inclination is less; for, at Buda, 900 miles from the mouth of the river, its height, according to Wahlenberg, is 229 feet, which gives a fall of three inches *per* mile, for the lower part of its course. In general, the rivers of Russia, Poland, and the north of Germany, flow over a more level surface, and are more navigable, than those of the south of Europe. Professor Robison states, on the authority of the Abbe Chappe, that the sources of the Wolga are but 480 feet above the ocean (*Ency. Brit.* article RIVER); but, as the Caspian Sea, in which this river terminates, is found to be 324 feet below the Black Sea (*Ann. Phil.* VIII. 391), this increases the space through which the waters of the Wolga descend to 804 feet, in a course of 2000 miles. The average fall may therefore be about two inches and a half *per* mile.

Islands. The islands of Europe, including Nova Zembla and Iceland, occupy a space equal to 280,000 square miles, or one eleventh part of the surface of the Continent; and of this space, the area of the British Isles amounts to rather less than one-half. The Black Sea is the only large sea connected with Europe, in which there are no islands worthy of notice.

Inland Seas. Mediterranean. The Mediterranean, the noblest inland sea in the world, forms the southern boundary of Europe, separating it from Africa, and partly also from Asia. It may be considered as the bottom of a vast basin formed by the Pyrenees, Alps, Mount Hemus, Taurus, Libanus, and Atlas. These mountains are every where near its shores, which are consequently narrow and much inclined. Hence there are no such extensive plains as Hungary or Poland near the coast of this sea, and hence also no very large rivers fall into it except the Nile; and, altogether, it receives a smaller quantity of water from rivers than the Black Sea or the Baltic, though six times larger than either. Its length is about 2350 miles; its breadth is extremely various, and its surface (exclusive of the Black Sea) is nearly equal to 1,000,000 of square English miles, or something less than one-third of the Continent of Europe. It is generally of great depth, and its numerous islands, which have uniformly a rocky surface, appear to be the summits of marine mountains.

Baltic. The Baltic, the greatest inland sea that is entirely in Europe, is about 1200 miles long, of very unequal breadth, and presents a surface of 175,000 square miles, exclusive of islands. It occupies the bottom of another large basin, 850 miles in breadth, and 1400 in length, extending from the Norwegian mountains, on the north and west, to the Carpathians on the south, and to the high lands in which the Dneiper, Don, and Wolga rise on the east. This basin, equal to one-third of the surface of Europe, has a very different character from that of the Mediterranean. The mountains are not very elevated, and are so placed as to leave a large track of land very little inclined between them and the Baltic, over which, especially on the south side, many considerable rivers flow with a gentle current. Hence, the country round the Baltic is much more level than round the Mediterranean; lakes are numerous in the low grounds, from the want of declivity; the sea itself is comparatively shallow, and receiving a much greater quantity of river water, it is much inferior in saltness. The commerce of the Baltic is annually interrupted by the ice, which endures four months in the Gulfs of Bothnia and Finland. The whole of this inland sea has sometimes been frozen over for a short time, but this is rare.

Black Sea. The Black Sea, which belongs only partly to Europe, is 690 miles long, 360 miles broad, and, including the sea of Asoph, presents a surface of 170,000 square miles, being almost of the same magnitude as the Baltic. It derives four-fifths of its water from Europe, and is curiously distinguished from the other seas of Europe, by its being almost totally without islands.

White Sea. The White Sea is 450 miles in length, of a very irregular figure, and occupies a space equal to 85,000 square miles. It receives some considerable rivers, but is frozen during six months of the year.

Lakes. The lakes of Europe are numerous, and are of two kinds; those which lie in cavities at the foot of high mountains, which are generally deep; such as the lakes in the Alps; on the east side of the Norwegian mountains; and among the mountains of England and Scotland; and those which are formed in level countries from the want of a sufficient declivity to carry off the water, such as the lakes in Finland, Poland, and Brandenburg. Four-fifths of the lakes of Europe are in the country round the Baltic.

Soil and Productions. The soil of Europe has neither the extremes of luxuriance nor sterility which belong to the soil of the other great continents. If it does not yield the rich fruits of tropical climates, it is not deformed by the burning sands of Africa, or the pestilent swamps of America. It does not pour forth its riches spontaneously, but, soliciting the care and the labour of man, it requites his industry with what is necessary to supply his wants; and, by exercising and sharpening his powers of mind, gives birth to those arts which place the productions of the most favoured climates at his disposal. Many of the plants which have been domesticated in Europe are natives of distant countries. The vine, the olive, and the mulberry, are said to have been brought from Syria by the Greeks; the Arabians introduced cotton; maize was received from the Indian tribes of America; the walnut and peach come from Persia; the apricot from Armenia; and the sugar-cane from China. There are not very many plants belonging to the tropical regions that absolutely refuse to grow in Europe, but an enlightened economy finds other productions more profitable. Besides sugar and cotton, the banana, the orange, citron, fig, pomegranate, and date, grow in the south of Europe. But the more delicate fruits are confined to southern latitudes, and disappear one by one as we advance northward. And it is worthy of remark, that the zones in which they grow generally follow the lines of equal summer heat, and run obliquely across the Continent in the direction of south-west and north-east. If a line is drawn on the map from Brest to Konigsberg, skirting the southern shores of the English Channel, and the Baltic, the zones that limit the growth of different plants run nearly parallel with this line. (Young's *Travels in France*, I. 306.) This holds generally in the south and middle of Europe; but in the extreme northern parts, and especially with regard to plants that require a moderate heat continued for a considerable time, the lines that limit the growth of certain vegetables seem to follow a different course, and decline towards the south as we advance eastward, in consequence of the increasing severity and length of the winter. It is scarcely necessary to say, that the zones, traced as proper for different plants, only mark the limits within which their cultivation is found advantageous. Most of them will grow beyond these limits; but they either require some peculiar advantages of soil or situation, or they are less profitable than other kinds of produce.

Vegetable Productions.

The sugar cane, one of the most desirable tropical plants, grows in Sicily and the south of Spain, in the latitude of 37° and 38°. The culture of it, which was once extensive in the latter country, has not been entirely abandoned, even since sugar was procured from the West Indies. Cotton is cultivated in the south of Spain on a small scale, to a greater extent in Sicily, the south-east angle of Italy, and in Greece and its isles, as high as the latitude of 41½°: we find it again a little beyond the eastern limits of Europe, at Astrakan, in the latitude of 46°.* The orange and lemon come to perfection in the west of Europe, only in the countries to the south of the Pyrenees and Apennines, within the latitude of 43° in Spain, and 44° in Italy. The olive does not succeed on the west coast of France in the latitude of 43°, but grows as far north as 44° or 45° on the east of France, and in Italy. Attempts to raise it at Astrakan, in latitude 46°, have not succeeded, on account of the rigour of the winter. The fig and the pomegranate, which accompany the olive in the west of Europe, are found in the Taurida in the east, at the latitude of 46°, where the olive will not grow, a proof that these trees bear the winter cold better. (Young's *Trav.*, I. 311; Storch, II. 309.) The climate proper for maize is found to terminate on the west coast of France at 45½°; on the Rhine at 49°; on the Elbe at 50° or 51°. Rice has nearly the same geographical range, but requires a peculiar soil and situation.† The culture of the vine extends as far north as the latitude of 47½° on the Atlantic coast; on the Rhine to 50½°; and on the Oder to 52°. In Russia it grows as far north nearly as 52°, but is not cultivated beyond 50°. (Young, I. 306; Storch, II. 310, 323.) The mulberry generally accompanies the vine. The limits of the culture of the common cerealia are not so well defined, as the necessities of man oblige him to raise corn under the most unfavourable circumstances. In a general point of view, however, the parallel of 57° or 58° may be regarded as the northern limit of the cultivation of wheat in Europe. It is raised as far north as 60° or 61° in Finland, but only in some favoured spots. In Russia, generally, it is chiefly confined to the provinces under the latitude of 57°. (Thomson's *Trav. in Sweden*, 409. Storch, II. 229, 240.) The harder cerealia, rye, oats, and barley, are cultivated in some sheltered situations on the coast of Norway, as high as the latitude of 69° 55′. But on the east side of the Norwegian mountains, these grains scarcely ripen in the latitude of 67° or 68°; and farther east in Russia, it has been found impossible to carry cultivation of any kind beyond the latitude of 60° or 62°. Barley, which accommodates itself better than any other grain to these high latitudes, by shortening the period of its growth, is sown and reaped within the space of seven or eight weeks. But the introduction of potatoes promises to be of vast advantage in these cold regions, as this plant thrives and yields a produce of thirty or fifty fold in places where grain often will not ripen.‡ Peaches and apricots succeed with much care as far north only as the latitude of 50° in Russia; melons as far as 52°. The plum and the cherry grow wild as far north as 55°, but are carried farther by cultivation. (Storch, II. 302, 304, 308.) Fruit-trees and the oak terminate in Sweden, at Geffle, in the latitude of 61°; but the pine and the birch advance within the arctic circle; and the former grows to the height of sixty feet in the latitude of 70°. (*Annals of Phil.* VII. 382.) The black-berry and the whortle-berry grow in Lapland, and the gooseberry even in Greenland. (Mentelle et Malte-Brun, *Geog.* I. 502.) Tobacco is extensively cultivated over the greater part of the Continent of Europe, from Sicily to Sweden. Flax and hemp have as extensive a range as corn, but they are raised in the greatest perfection between the latitudes of 45° and 60°.

* Laborde's *View of Spain*, II. 122–125. Storch, *Tableau de la Russie*, II. 250. Mentelle et Malte-Brun, X. 128.

† Young, I. 306; Malte-Brun, *Precis*, II. 508; MS. Travels in Germany.

‡ Storch, II. 209, 244, 304, 370; Von Buch. *Ed. Rev.* XXII. 163, 171; Crome, *Allgemeine Ubersicht, der Staatscraft von den Samtlichen Europaischen Reichen und Landern*, 1818, p. 108; Malte-Brun, *Precis de la Geographie Universelle*, 1812, II. 508.

We have stated, that the superficial extent of Europe is about 3,432,000 square miles. If we draw a concave line from a point in the Uralian mountains, about the latitude of 60° or 61°, to the west coast of Norway, in the latitude of 69°, passing through the Lake Onega, and a little to the northward of the Gulf of Bothnia, this line will mark the extreme limits of cultivation, and will cut off a space equal to 550,000 square miles, or nearly one-sixth of Europe. The space cut off, however, is not entirely useless, as a part of it produces pasturage and wood. The cultivation of rye, oats, and barley, is confined to the region south of this line, and includes more than five-sixths of Europe; but in the northern parts of this zone, only a very small proportion of the land will bear corn. The region adapted to the cultivation of wheat comprehends about four-sevenths of Europe, and includes all the densely peopled parts. The region of the vine extends over three-sevenths of Europe.

Metals. Europe, in proportion to its extent, is probably richer in mineral wealth than the other quarters of the globe. It contains all the metals except platina; and though it affords gold and silver only in limited quantities, iron, copper, lead, with coal and salt, commodities of greater value to society, are abundant and widely distributed. The mountains, consisting of primitive and transition rocks, are the great depositaries of these mineral treasures.

Iron. Iron is found in all the chains of mountains in Europe. The richest mines are in the Dofrines, or Scandinavian Alps. But rich mines are also found in the Alps of Stiria, Carinthia, and Bavaria; in the Pyrenees, the Vosges, the Cevennes, the coal district of Britain, the Urals, the Carpathians, the Hartz, and many other places.

Copper. Copper is also widely distributed, though less abundant than iron. The richest mines are in Hungary, in the Carpathian mountains. It abounds also in the Saxon and Bohemian mountains, in the Dofrines, the Urals, the north of England, and the Alps; and it is found in the Vosges, the Pyrenees, and other mountains of Spain, in the north of Germany, and in Tuscany.

Lead. Lead exists in the Alps, Carpathians, Pyrenees, Cevennes, Vosges, the British mountains, and the Urals.

Tin. Tin is found only in a few places in Europe. The richest mines are in Cornwall; next to these are the mines in the Erzegebirge. It is also found in Hungary and Spanish Gallicia.

Mercury. Mercury, like tin, is confined to a few places. The mine of Idria, in Austria, which yields 8000 to 10,000 quintals *per annum*, is the most productive in Europe. There are also considerable mines at Deux Ponts, in the Palatinate; in the Spanish province of La Mancha, and in Transylvania.

Gold. Gold is widely diffused through Europe, but generally in such quantities as not to repay the expence of working. It is wrought, however, in the Carpathians, the Urals, the Dofrines, the Alps, and it is said, in Ireland. Anciently there were rich mines of gold in Spain and Greece.

Silver. Silver is more abundant than gold, though less widely distributed. There are productive mines of this metal in the Erzegebirge, the Carpathians, the Urals, the Norwegian Dofrines, and in Sardinia. It is found also in the Alps, the Vosges, and the Sierra Morrena.

Coal. Of coal the richest mines are found in the north and west of England. It abounds also on both sides of the south of Scotland; in Ireland, in the Netherlands, in one-fourth part of the French territory; and occurs more sparingly in Saxony, Hanover, Denmark, Sweden, Russia, Hungary, Bohemia, Moravia, Silesia, Bavaria, Austria, Franconia, Westphalia, Swabia, Catalonia, and some other parts of Spain, in Portugal, and in Sardinia. After Britain, France is the country in Europe best supplied with this mineral. The produce of the French coal mines has increased fourfold within the last twenty-five years. (*Ann. Phil.* VII. 314.)

Salt. Salt is procured from the waters of the ocean, and, in the interior of Europe, from numerous salt mines and salt springs. The most productive salt mines in Europe are those in Poland, on the north side of the Carpathians; and those in Salzburg, on the north side of the Alps, both of which belong to Austria. There are also extensive depositaries of mineral salt in Transylvania and Hungary; in Valentia, Navarre, and Catalonia, in Spain; in Cheshire, in England, and in Bavaria and Switzerland. Salt springs are numerous along the sides of primitive mountains in most countries of Europe. The most extensive salt mines of Russia are in Asia.

Antimony, cobalt, zinc, manganese, sulphur, alum, and a great variety of other mineral productions, are found in Europe; but it is unnecessary to specify their localities.

It is observed, that the Alps, Pyrenees, Carpathians, and other mountain chains which run east and west, are richest in metals on the south side; while the Dofrines, Urals, and others which run north and south, are richest on the east side. Of the mountain chains of Europe, the Apennines are the poorest in metals, the Carpathians probably the richest. (Pinkerton's *Geog.* Mentelle et Malte-Brun,) *Geog.*)

Different races of inhabitants. The present population of Europe is sprung from a variety of tribes, but authors differ much as to the number and peculiar characters of the original races. It would serve little purpose to enumerate the contradictory hypothesis which have been advanced on this subject. We shall, therefore, rather confine ourselves to an account of those more obvious general characters, founded on language, manners, or physical constitution, which distinguish the different portions of the population of Europe at present.

The nations in the south-west of Europe, the French, Italians, and Spaniards, speak languages in which the Latin idiom predominates. They have generally black hair and black eyes, are rather inferior in stature to the Gothic nations, but gifted with more imagination, and a higher degree of organic sensibility; they are more temperate, more inventive, but less persevering.

The Gothic race includes the English, Swedes, Norwegians, Danes, Dutch, and the various German nations inhabiting the country between the Rhine and the Oder, with the Swiss, Bavarians, and a part of the inhabitants of Bohemia, Moravia, and Austria. These nations are distinguished by fair hair, blue or grey eyes, large stature, and a clear complexion. They have less imagination than the southern nations, are more addicted to pursuits that exercise the understanding, are more thoughtful and serious, and less temperate in drinking.

The Sclavonic nations occupy the east of Europe generally, including Russia, Moldavia, Poland, ancient Prussia, with the greater part of Silesia, Hungary, Moravia, Bohemia, Croatia, and Sclavonia. They are rather lower in stature than the Gothic race, the countenance is shorter, but more animated, and the hair black. The prevailing religion is the Greek Christian, and in the western parts the Roman Catholic. They all speak dialects of the Sclavonic language, of which the Russian is one.

The remains of the Celtic tribes are found in the Highlands of Scotland, in Wales, Ireland, Britanny, and Biscay in Spain. They are rather low in stature, have lively eyes, prominent cheek bones, red or yellow hair in the north, but sometimes black hair in the south.

The Finns in the north of Europe have a language of their own, and the characters of a peculiar race. They have light brown eyes, a pale complexion, cheeks hollow, are of middling stature, but heavy and muscular.

The Samoieds, Laplanders, and other tribes who live within the polar circle, are distinguished by their very low stature, the smallness of the legs and feet, and largeness of the head, prominent cheekbones, small round black eyes, black and bristly hair, and a swarthy skin. The Laplanders, from intermixture with the Finns, Russians, and Norwegians, have lost, in some degree, the characteristic traits of the original race.

The modern Greeks and Albanians are supposed to be descended chiefly from the ancient inhabitants of the country, whose language they have preserved. They have a greater resemblance to the Latin nations than to those of the Gothic race. The Turks are an Asiatic tribe.*

Progress of Civilization.

Europe has been gradually advancing from poverty and barbarism to wealth and refinement since the tenth century, but the progress of the different nations has been very unequal. No single cause has contributed so much to their improvement as commerce; and hence the first advances have always been made by maritime states; and the progress of the different communities has been nearly in proportion to their vicinity to the sea, or the facility of their communication with it. The small republics of Italy and the Hanse towns were the seats of industry, wealth, knowledge, and freedom, while slavery, ignorance, and rapine, reigned in the countries around them. The tendency of commerce to enrich a country seems to depend on its power to create disposable capital. Though a certain species of opulence exists among the great landholders of agricultural countries, those masses of disposable capital which give vigour to industry, and supply the means of great improvements, are only found in commercial states. Commerce also favours the growth of manufactures, and these two species of industry raise up a middle class closely allied with the great body of the people. It is among this class that ideas of civil and religious liberty take their rise, and find their firmest supporters; whereas in countries entirely agricultural, liberty means only the domination of the aristocracy. The spirit of liberty once introduced, laws are improved, prejudices hostile to industry extinguished, and new vigour infused into every branch of society. It is thus that freedom and wealth have generally followed in the train of commerce; and that the commercial states have led the way in those improvements which have so much ameliorated the condition of Europe. When the Italian republics flourished, however, Europe was not in a state to be much benefited by the lights their experience afforded. The Dutch republic, which flourished at a later period, gave a more striking demonstration of the advantages of industry, freedom, toleration, and good government, at a time when neither liberty nor toleration were understood even in England, and when industry was in a very low state all over Europe. The example of the Dutch furnished statesmen with new ideas, and had a sensible influence on the policy of England, France, and other countries. The genius of Peter the Great derived from this small republic the seeds of those improvements by which civilization was spread over the vast empire of Russia. The superiority which the Dutch possessed has since been transferred to Britain, and she has acquired with it the privilege of instructing other nations in the sources of public wealth, and the science of government.

The Reformation had a material effect in accelerating the progress of society. It put an end to a multitude of abuses and prejudices adverse to improvement, and inspired the human mind with a new activity. Those countries in which it took no root seemed to have had their progress suddenly arrested, while others, less favoured by nature, derived new life and vigour from its influence. Italy and Spain, now so far behind Britain, France, and Germany, were the first countries in Europe for knowledge, wealth, and industry, at the period of the Reformation. The establishment of the Protestant religion produced a more liberal spirit among the Catholics in those countries where the two churches exist together; but in those countries where protestantism has never obtained a footing, the dread of its introduction has thrown the government more and more into the hands of the clergy; the clergy, armed with power, have become more jealous and intolerant, and have nearly put an end to all freedom of thought. The literary glory of Spain expired some time after the Reformation, and Italy has been checked in her career. The older writers of these countries breathe a spirit which would not be tolerated at the present day, nor does society there afford the elements out of which such characters could be formed. And thus it happened that the very same event which called forth the powers of the human mind in the north of Europe, extinguished the intellectual activity of the south.

---

* Mentelle et Malte-Brun, I. 540.—M. de Stael, *Germany*, Introduction.

The improved means of internal communication in countries in modern times, have had a considerable effect upon the state of society. In ancient times free states were necessarily small, because when neither the press nor the post existed, that union of sentiment, necessary to control the conduct of men in power, could not be effected among a large population scattered over a wide space. A number of free states sprung up in Greece, because that country, perforated by mountains and arms of the sea, afforded natural means of defence to such small societies as could then exercise the functions necessary to the preservation of freedom. It is a mistake to suppose that, in these states, a greater extent of territory could have been united under one government by adopting the representative system. The resolutions of a body of representatives would command no more respect from a government than those of as many private individuals, if they were not constantly supported by the opinions of the mass of society; and this requires such a rapid and general circulation of intelligence as could not then exist. The small size of the Grecian states was a necessary condition of their freedom; but it was a serious disadvantage, not only because it lessened the commercial intercourse between the different parts of the country, but because such small communities had not strength enough to resist a great force from without; and hence these states fell a prey to the superior power of the Macedonian monarchy. The whole of the south-west of Europe exhibits the physical features of Greece upon a larger scale. Its surface is broken into numerous sections by gulfs and mountains, and abounds in natural barriers. Favoured by these circumstances, the different communities in this quarter of the world in modern times, enjoyed a certain degree of independence and security, which hastened their progress in civilization. Russia, which occupies the only large plain in Europe, has been the last reclaimed from barbarism. So long, however, as the means of communication remained very imperfect in modern Europe, free governments were confined to small states, and the large were abandoned to feudal tyranny or military despotism; but the science of government has gradually improved, as knowledge, commerce, and the arts, have advanced; and, at present, the admirable inventions of the post and the press give such an electric rapidity to the circulation of public sentiment, that twenty millions of men could be as easily united in defence of their rights as the small population of Attica, in the time of Xerxes.

The progress of improvement tends to level all distinctions between states, but those founded on the extent of their natural resources. Capital, skill, intelligence, and all acquired advantages, tend to an equilibrium. When Europe was overrun with barbarism, the city of Venice, by its commercial wealth, was a counterpoise to two or three of the great monarchies of the Continent. The discovery of America, and of a passage by sea to the East Indies, gave a new direction to commerce, and undermined the greatness of that city. The Dutch republic rose by its freedom and industry, and was able, in the time of Charles II. to dispute the empire of the sea with the combined powers of England and France. But England increased her commerce, and improved her constitution, and having a larger and more fertile territory, as well as a greater population, she at length obtained an ascendancy over Holland, deprived her of the empire of the sea, and stript her of most of her colonies. At the beginning of the seventeenth century, Spain and Turkey were the first powers in the west and east of Europe, and inspired their neighbours with the dread of conquest. Sweden ruled with undisputed sway in the north; and Russia, now so formidable, was scarcely known. Spain, under a better government, might recover a part of her influence, but the Turkish empire seems near its dissolution; and the importance of Sweden and Holland is gone irretrievably, in consequence of the growing strength of the neighbouring powers. The extent of territory and immense natural resources of Russia must, in the end, raise her to a decided superiority over all the other powers of Europe, if the empire does not fall to pieces from its own weight, or get into disorder from the vices of its government. Its progress hitherto has been greatly aided by the personal characters of its sovereigns. If we were to judge merely from the advantages which different states possess for raising and supporting population, we might predict that, in the course of a century and a half, Russia would rule with uncontrolled sway over the old Continent, and the United States over the new; and that the other states, which now figure in the first rank in either hemisphere, would then owe their existence, like the small principalities of Europe at the present day, to the forbearance, or the mutual jealousy of their powerful neighbours. But, in the course of events, many changes may occur to give a different destiny to both Continents.

Number of Inhabitants.

The number of the inhabitants of Europe has been progressively increasing during last century, slowly in the earlier part of the century, but more rapidly as we approach the present times. Apparently it has been least considerable in Spain, Italy, Sweden, France, and Germany; rather greater in Prussia, Austria, and the British Isles; and greatest in Russia. Within the last thirty or forty years, the advance has been very perceptible, even in the countries which suffered by the war. When we compare the statements of the populations of the different districts of Prussia, Austria, and Germany, as given in Hoeck's Tables, between 1790 and 1799, with those given by Hassel, in 1815, we find an increase almost everywhere. In 1787, Zimmermann estimated the population of Europe at 144,000,000; at present, according to the best authorities, it is about 184,000,000. This exhibits an increase of 40,000,000 in 32 years, which implies an annual augmentation of 7,7 in the 1000, or 1,416,000 persons on the present population; and at this rate the number of inhabitants would double in about 90 years. There is no reason to think that this result differs materially from the true average during this period. In Britain, Russia, Silesia, and some other countries, the rate of increase has been still more rapid. The most obvious cause of this increase of population is the increase of production, from the improvement of agriculture and the arts; but part of the effect may be ascribed to the general introduction of potatoes in many countries, by which the same portion of ground is made to support three or four times as many persons as it would under corn. In France, where Mr Young, in 1789, found the cultivation of potatoes extremely limited, it is now so much extended, that, according to Chaptal, the annual produce is nearly 20,000,000 *hectolitres*, or 55,000,000 bushels,—a quantity fully as great in proportion to the population as Mr Colquhoun assigns to Britain and Ireland. This augmentation of numbers does not appear to have been accompanied with any deterioration in the habits of the people. On the contrary, the diminution in the rate of mortality which has taken place in Britain, France, and Sweden, is a decisive proof of an improvement in the condition of these countries; and by analogy, we may extend the same conclusion to the other parts of Europe. It may be remarked, that the general extension of commerce, and the accumulation of capital, render a season of scarcity, in a particular country much less destructive now than formerly. In Britain, whose commerce and capital enable her to draw supplies from all parts of the world, the additional mortality, in the most severe scarcity, does not exceed one-tenth; but, in Sweden, a poor country, it sometimes amounts to one-third. (Milne's *Annuities*, p. 409.) In ancient times, when each country depended entirely on its own produce, the effects of a scarcity were dreadful.

Number of States, and their Comparative Importance.

The states of Europe at present are 57 in number, and, considered with respect to political importance, may be divided into four classes. Britain, France, Russia, Austria, and Prussia, belong to the first; Spain, Sweden, Turkey, and the Netherlands, to the second; Portugal, Naples, Bavaria, Sardinia, Denmark, Saxony, Wirtemberg, Hanover, and Switzerland, to the third; Baden, Tuscany, and the States of the Church, with the other small states of Germany and Italy, belong to the fourth class. Objections may be made to this classification, but we have not been able to find a better; and a few remarks will explain the principle on which it is founded. The first five powers are the only powers that exercise a decided influence over their neighbours; and it is by their joint counsels that differences among the smaller powers are adjusted, and all questions that concern the general state of Europe decided. The four states of the second class visibly occupy a lower place in the scale of power than those of the first. They have very little exterior influence, but they are not directly controlled by any of the stronger powers; and it is only among them and the states of the first class that wars are now likely to originate. The third class includes those states which are too feeble, and too much under the influence of the great powers to become principals in war, but are of importance enough to be valued as auxiliaries by states of the first and second classes. The fourth class consists of states which have too little force to maintain any degree of independence, and owe their existence to the justice, the forbearance, or the mutual jealousies of the stronger powers. It is only in Europe that small states exist among large ones; and their existence is the consequence of that equality of power among the great states, which compels each to respect the rights of the others, and to pay a certain degree of deference to public opinion. The close union among four of the powers of the first rank since 1813, has established their influence over the rest of Europe much more firmly than at any former period.

Statistical Sketch of the more considerable Powers.

A *detailed* account of the principal European States is given under the proper heads in the ENCYCLOPÆDIA, or in this SUPPLEMENT. Our object here is only to bring together such *general facts* as will afford a comparative view of the internal condition, power, and resources of those larger societies which comprise the greatest part of the population of Europe. With respect to the smaller states, we cannot make room for any further details than what are contained in the TABLE, which forms the conclusion of this article.

BRITAIN.

Though much smaller in extent than any of the other states of the first rank, Britain is the most wealthy and powerful of the whole. She has a moderately good climate, a soil less fertile in grain than that of France, but affording better pasturage; an extensive line of sea-coast with numerous harbours; a natural and well defined frontier, a good commercial position, and the largest fields of coal in Europe. But all these advantages have contributed less to her aggrandisement than the excellence of her laws and constitution. The progress of Britain in commerce, manufactures, and agriculture, within the last century, and especially within the last 40 years, has been wonderfully great.

The British Isles contain about 76,000,000 of acres, of which about 49,000,000 are in cultivation, and 27,000,000, or more than one-third, waste or uncultivated. About one-half of the waste-land is in Scotland, where the cultivated soil forms only 26 parts in the 100 of the whole surface of the country; in England it forms 82 parts in the 100, and in Ireland 69.* The agriculture of Britain, compared with that of the Continent, is distinguished by the farms being generally larger, the plan of cultivation more systematic and skilful, the produce on equal soils greater, the pasture land bearing a higher proportion to the land in tillage, and the breed of animals being superior. In Scotland the pasture land forms about one-half of the land in cultivation; in England four-sevenths. The whole annual produce of grain in Britain and Ireland is estimated by Dr Colquhoun at 35,000,000 of quarters, excluding seed; of which, wheat is supposed to form 26 parts in the 100 in quantity; barley 17 parts, oats 49, rye 2, pease and beans 5. The value of the annual produce of grain is computed by the same author at L.73,700,000; that of the pasture land at L.89,200,000; and the whole gross produce of all the branches of agriculture, including gardens and cattle, at 216,000,000. But as this estimate was made in 1812, when prices were uncommonly high, a third or a fourth should be deducted for the present value. The valued rack-rent of England and Wales, as returned to Parliament by the Commissioners of Taxes in 1810, was L.29,503,073, which gives 15s. 6d. as the average of rent of all kinds of land *per* acre. The rental of Scotland in 1813, according to Sir John Sinclair, was L.5,041,779, including mines and fisheries; and deducting L.341,000 for these, the rent of land will be L.4,700,000, or 4s. 11d. *per* acre on an average. (*Pamphleteer*, X. p. 94.)

---

* Colquhoun's *Treatise on the Wealth, Power, and Resources of the British Empire*, 1815, p. 56, 57. Sir J Sinclair, *Pamphleteer*, X. 94.

The progress of Britain in manufactures has been still more rapid, within a recent period, than in agriculture; and her natural advantages for this species of industry are perhaps more exclusive. She has a good supply, within herself, of the raw material for all her staple manufactures except cotton; and her means of procuring this article are, at least, equal to those of her neighbours. The growth of this manufacture in Britain has been unprecedently rapid. In 1767, the value of all the cotton goods manufactured did not exceed L.200,000; and, in 1812, it was estimated at L.29,000,000. The produce of the woollen manufactures, in the same year, including the raw material, was estimated at L.26,000,000; that of leather at L.15,000,000; of linen at L.15,000,000; and the whole produce of manufacturing industry, *exclusive* of the value of the raw material, at L.114,000,000. (Colquhoun, p. 91.)

The commerce of Britain seems to have increased pretty regularly during the first sixty years of the last century; but, from 1760 to 1786, it remained almost stationary. From this period to the present time, the increase has been rapid beyond example. The exports of England, about 1700, were L.6,045,000; in 1760, L.14,694,000; in 1786, L.15,385,000. (Chalmers, *Hist. View*, p. 315.) In 1818, the official value of the exports of the United Kingdom was L.53,559,711; of the imports, L.36,900,681, exclusive of the trade between Britain and Ireland. The mercantile tonnage in 1818 was 2,674,468, including that of the colonies, and the number of seamen 173,609. (*Parliamentary Papers.*) The annual produce of foreign commerce, or the sums derived from it by all classes concerned in it, were estimated, in 1812, at L.46,373,478; the gains from inland trade at L.31,500,000; and the whole annual produce of industry, from all sources, at L.430,000,000. (Colquhoun, p. 96–100.)

The growing wealth of Britain has had to sustain an increasing weight of public burdens. The public revenue of England, at the Union in 1709, was L.5,691,803; of Scotland, L.160,000. In 1763 (a year of peace) the nett revenue was L.9,100,000; in 1790, L.15,986,068; and, in 1812, it was L.64,979,960, of which England furnished L.55,995,123, Scotland L.4,155,599, and Ireland L.4,882,264. (Colquhoun, p. 262.) In the year ending 5th January 1819, the nett revenue was L.55,741,098, which was collected at an expence of L.8, 6s. 4¼d. *per cent.* The nominal amount of the national funded debt, at 5th January 1819, was L.802,296,265, including about L.7,000,000 of loans to Austria and Portugal; the unfunded debt was L.51,992,095. The interest on the funded debt was L.27,999,389; adding to this L.2,500,000 for interest on unfunded debt, we have L.30,500,000; and, assuming the true rate of interest to be 5 *per cent.*, the capital of the national debt may be valued at L.610,000,000. The army, on the 25th January 1819, was 104,369 men. The navy consisted of 173 ships of the line, and 448 of inferior size, including ships building, with 20,000 seamen. (*Parliamentary Papers; Navy List.*)

The population of England appears to have doubled in the 100 years ending 1811; that of Scotland appears to have increased one-half in the same period; that of Ireland is supposed to have doubled within the short space of 46 years. (Colquhoun, p. 10.) In the period between 1801 and 1811, the rate of increase, in England and Scotland, was such as would have doubled the population in 52 years. (Milne, *Ann.* p. 112.) This rapid increase of numbers appears not to have been accompanied with any deterioration of condition, at least in the people of England and Scotland. In the five years ending 1784, the annual mortality in England and Wales was 1 in 37; in the five years ending 1810, it was 1 in 47.86. The average number of poor relieved in these 10 years was 1 in 8, 9, or nearly one-ninth of the inhabitants. (Milne, p. 437-442.) Of the population of Britain and Ireland, about 35 families in the 100 are employed in agriculture, 45 in trades, manufactures, and handicrafts, and 20 in other occupations. The total population of Britain and Ireland, in 1819, according to the rate of increase indicated by the returns for 1801 and 1811, should be about 18,740,000. To these must be added about 875,000 British subjects in the various colonies, and about 45,000,000 of native inhabitants and negroes, making a total of 64,615,000 persons. (Colquhoun, p. 7.)

FRANCE.

This country enjoys, upon the whole, greater natural advantages than any other in Europe. Her territory is above one-half larger than Great Britain and Ireland, and is superior in soil and climate. She has a greater proportion of arable land than any of her neighbours; the natural means of communication between her provinces are abundant and easy; she is well provided with all the useful metals except tin, and is better supplied with coal than any other country in Europe except Britain. When we add to these advantages the intelligence and activity of her population, and consider that corvees, tithes, feudal services, and most of those abuses which shackled her industry, are now removed; that she is likely to enjoy the benefits of good laws and a free constitution, and is not encumbered with a great national debt, we cannot doubt that, if peace continue for any considerable length of time, she will yet rise to a much higher degree of wealth and prosperity than she ever before possessed. Even during the distractions of the Revolution, though her commerce was annihilated, her agriculture and manufactures have been extended and improved, her population has increased, and their condition has been ameliorated. The greatest bar to her progress will probably be the extreme division of property; and, for some time, the want of capital.

The surface of France contains within its present limits 52,000,000 hectares, or 128,000,000 acres. From partial surveys, for fiscal purposes, made in each department, it is estimated that the waste land, including roads and rivers, amounts to one-eighth of this, or 12 parts in the 100; the arable land to 44 parts in the 100; the woodland to 14 parts, the pasturage land and meadows to 14, the vineyards to 4, wild land 7, quarries, buildings, orchards, gardens, olive and other plantations, make up the remaining 5 parts. (Chaptal, *de l'Industrie Françoise*, I. 205. Paris, 1819.) In addition to the vegetable productions that grow in England, the climate of France enables her to raise maize, vines, olives, mulberries, and chesnuts; and by some of these a produce is extracted from soil which, in England, would yield nothing. The whole produce of grain in France is estimated, by Chaptal, at 143,000,000 hectolitres, equal to 50,000,000 quarters, or 40,000,000, deducting one-fifth for seed, which is only 5,000,000 above the produce of Britain and Ireland, as estimated by Colquhoun. Of this produce of grain, wheat forms 36 parts in the 100, rye 21 parts, maize 4½, buckwheat 6, barley 9, oats 22, legumes 1. The quantity of potatoes (19,800,741 hectolitres) is equal to two-thirds of the rye. The produce of 4,000,000 of acres planted with vines, in 1808, was 37,600,000 hectolitres of wine. (I. 173, 177.) The *annual gross produce* of the land, which was estimated, by Arthur Young, at L.230,000,000 Sterling, is estimated, by Chaptal, at 4,678,000,000 of francs, or L.187,000,000 Sterling,* of which the principal items are,

Corn and legumes (secs), .	L.77,172,000
Vines, ...	28,757,000
Forage, ...	27,322,000
Wool, ...	3,253,000
Raw silk, ...	617,000
Hemp, ...	1,237,000
Flax, ...	760,000
Woods and forests, ...	5,657,000
Cattle, sheep, and swine, . .	17,880,000
Poultry, ...	2,588,000
Fruits, ...	2,584,000
Pulse and other esculent vegetables (legumes frais), ...	7,872,000

(Chaptal, I. 226–288, Young, I. 468.)

Revenue imposable.

The mean revenue derived from a hectare of land is estimated at 28 francs, or 22s. 6d. equal to about 9s. 1d. *per* acre; and the revenue of the whole departments, calculated on this basis, is L.59,449,000; but, calculated according to the reports of special Commissioners, in 1815, it is L.65,040,000. The last sum includes houses, and may be considered as corresponding nearly to the rackrent of lands and buildings in France. (I. 208–212.) This is certainly too low. The average rent of all kinds of land in France was estimated, by Young, at 15s. 10d. *per* acre. (*Trav.* I. 476.) The most peculiar feature in French agriculture is the vast number of small proprietors, who cultivate their patches of land by their own labour. Arthur Young supposed that, before the Revolution, one-third of the property of the kingdom was held by such persons; and Chaptal says the number of proprietors is doubled within the last thirty years. The latter computes the whole number of farms in France at 3,000,000; so that, on an average, each cannot exceed 43 acres, including wastes. In the cultivation of good soils, the agriculture of France is nearly equal to that of England, but it is much inferior in the management of poor soils, in the system of cropping, and in the breed of animals. It has been much improved, however, during the Revolution, by the extensive cultivation of artificial grasses, by augmenting the live stock, by the general exclusion of fallows, and by increasing the cultivation of potatoes.†

The manufactures of France, amidst all the troubles of the Revolution, have been generally advancing, though some branches have retrograded. The number of workmen employed in Lyons, the principal seat of the silk manufacture, was one-fourth greater in 1812 than in 1789. France produces within herself about eleven millions of pounds of raw silk, and imports nearly as much; and the total value of the manufactured articles produced is estimated at L.4,300,000. Of wool, France produces about eighty-three millions of pounds (Avoirdupois), valued at L.3,253,000, and imports twenty-six millions of pounds; which, converted into various fabrics, is estimated to be worth L.8,000,000 Sterling. The value of the manufactures of flax and hemp is estimated at L.11,712,000. The spinning of cotton by machinery, which was scarcely introduced before the Revolution, employed one million of spindles in 1812; and there were 220 establishments for spinning cotton in 1818. The cotton imported in 1817 amounted to thirteen millions of kilogrammes, or twenty-eight millions of pounds, which, when worked into fabrics, is estimated to be worth L.7,664,000. This is only about one-fourth of the value of the cotton manufactures in Britain; but in France this species of industry has had to struggle with extraordinary difficulties. The manufactures of iron in France are estimated at L.8,292,000; those of leather at L.5,732,000. The whole gross produce of manufacturing industry, including manufacturers' profits, is estimated at 1820,000,000 of francs, or L.72,800,000, of which the value of the raw material forms 32 parts in the 100, wages 47, manufacturers' profits 10, and expences 11. (Chaptal, II. 116-120, 145, 203.)

---

* Reckoning the Pound Sterling equal to 25 francs, its real value at present is 25.2. See the article Exchange.

† Chaptal, I. 139, 144, 153, 224, &c. Birkbeck's *Tour in France*, 1814, p. 109.

With regard to the commerce of France, we have no satisfactory details to present for any recent period. According to Arthur Young, the commerce of France nearly quadrupled, between 1718 and 1786. (I. 520.) In the three years ending in 1789, the imports on an average were 613,543,000, and the exports 448,748,000 francs, or about 24½, and L.17,000,000 Sterling. (Chaptal, I. 134.) In the public journals (Magazines and Newspapers) we find the exports of France for 1818 stated at L.15,400 000.

The population of France, notwithstanding the interruption to industry, and the drains occasioned by the long wars, has increased since the commencement of the Revolution. According to calculations made by the National Assembly in 1791, France contained 26,363,074 inhabitants, and, in 1818, it contained 29,327,388 within the same limits. (Young's *Travels*, I. 479. Chaptal, I. 206.) This shows an augmentation of 4 in the 1000 annually; but in a period of peace, the rate of increase must be much greater. The condition of the labouring classes also appears to be improved. Wages, which Arthur Young estimated at 19 sous or 10d. English *per* day, throughout the kingdom for all kinds of work, were estimated at 1s. 5½d. *per* day, in 1814, by Mr. Birkbeck, who considers this sum as equivalent to 2s. 11d. in England. The annual mortality, which was estimated at 1 in 30 by Neckar before the Revolution, we find stated recently to be 1 in 35. (Malte-Brun, *Precis Geog.* II. 563.)

According to returns made in 1815, there were then in France 22,300 primary schools, with 737,379 pupils. There were besides 368 secondary schools, 36 lycees, and 26 universities.

The public revenue of France was estimated, in the ways and means for 1819, at 889,209,500 francs, or L.35,568,000. The public debt is stated at L.127,000,000, and the interest at L.9,666,000. The army 140,000. The navy, 40 ships of the line and 30 frigates. The secular clergy, according to Crome (p. 214), amount to 51,300, with 700 francs each of salary, besides 50 bishops, and 9 archbishops, with 15,000 and 25,000 francs a-year. We cannot believe the number to be so great. The revenues of the church, calculated on this basis, would amount to L.1,475,000. Before the Revolution they amounted to L.5,687,500, and lately we find them stated at 20,700,000 francs, or L.828,000 for 1817. (*Public Journals*; Young's *Travels*; Hassel.)

Acquisitions of France in Territory and Population from the commencement of the Revolution to the Peace in 1815.

		Square Miles.	Population.

able variations, not sensibly affecting her whole extent of territory, or amount of population.

AUSTRIA.

The Austrian empire is one-fourth larger than France, and twice as large as Britain and Ireland. Its population consists of a mixed mass of nations, differing in origin, language, religion, and manners, having few common ties, and little intercourse with one another. Austria has but a small extent of sea-coast, and is almost entirely an inland power. The climate is similar to that of France, but subject to greater extremes of heat and cold, the soil not much inferior, the grain and fruits nearly the same. She is richer in mineral wealth than any other state in Europe, and possesses coal, though not in great abundance. Her natural resources are capable of vast improvement, and in the hands of a wise and liberal government, would soon raise her far above the rank she now enjoys. Of the six sections into which her territories are divided, Lombardy is the most populous in proportion to its extent; Bohemia and Moravia are next in population, and are the seats of the chief manufacturers; Austria Proper and Hungary are remarkably rich in mines; and Galicia, though in a low state of cultivation, is fertile in grain, and contains the most productive mines of salt in Europe. Austria has but a slender title to be regarded as a German power; less than one-fifth of her population are Germans. The Sclavonic race, who form nearly one-half of the population, give a character of ignorance and backwardness to the government. In Bohemia, Hungary, and other provinces where this race predominates, vassalage exists in some of its forms, and cramps the progress of society. The Austrian empire, in truth, consists properly of six separate governments, feebly united under one head. Each of these governments, except that of Lombardy, has a diet or states, composed of the deputies from the nobility, clergy, and towns; but these bodies exercise no real influence over the government, except in Hungary, where the old feudal institutions remain in vigour, and the aristocracy have always maintained a great degree of independence.

The surface of the Austrian monarchy is estimated at 258,000 square English miles. Of this surface, the waste lands, including morasses, mountains, rivers, and ground covered with buildings, is estimated at 5 parts in 24, the useful soil at 19 parts in 24; and of the useful soil, about 43 parts in the 100 are in tillage, 9 parts meadow land, 9 parts commons, which support cattle, 2 parts vineyards, 2 parts gardens and orchards, and 35 parts forest land. The total produce of grain is estimated at 165,500,000 metzen, or about 35,670,000 quarters; consisting of, wheat 14 parts, barley 11, rye 31, and oats 44. In 1804, the net produce of a joch (equal to 1½ acre) of corn land, for the whole Austrian states, was valued, by Lichtenstern, at 5 florins (10s.), and of pasture land at 2 florins (4s.). (Hassel's *Stat. abris des Oest.* p. 90.) The annual produce of wine in the Austrian dominions is estimated at 36,000,000 to 40,000,000 of eimers (each equal to 14 English gallons), of which Hungary furnishes nearly two-thirds. This is rather more than one-half of the produce of the French vineyards. Galicia is the only province in which there are no vines. Hungary and Sclavonia supply 180,000 centners of excellent tobacco. The Ex-Venetian states furnish yearly 1,200,000 pounds of silk; Milan and the Tyrol nearly as much; and altogether this species of culture employs 400,000 persons. Flax, hemp, hops, and fruits, are also extensively cultivated; and the forests, which cover more than one-fourth of the empire, furnish an ample supply of wood. The total produce of the vegetable kingdom is valued at L.68,500,000 Sterling,—a small amount, considering the extent of the country; but agriculture, though there are numerous societies for its improvement, remains in a low state, from the prejudices of the higher classes, and the oppressions to which the peasantry are exposed. The horses in the empire are estimated at 1,800,000, the sheep at 12,000,000, and the horned cattle at 10,000,000: The live stock has greatly diminished within the last twenty-five years. The annual produce of the mines is 3846 marks of gold (the mark is about three-fourths of a pound Troy); 486 centners (hundred weights) of silver; 56,000 centners of copper; 30,000 centners of lead; 4890 centners of tin; 1,200,000 centners of iron; and 5300 centners of mercury. About 5,500,000 centners of salt are prepared, the greatest part from salt mines and springs. The annual produce of these minerals in 1802, when it was probably one-third less than the above, was valued at L.4,700,000.*

The leading manufactures are linen, cotton, woollen, silk, leather, and works in metal and wood. The linen manufacture existing in all the provinces, but to the greatest extent in Bohemia and Moravia, is supposed to employ 1,200,000 persons; the woollen manufacture 300,000 persons; the cotton 100,000: about 18,000 or 20,000 centners of cotton were spun by machinery in 1817, which is three times the quantity spun in 1803. The silk manufacture, which is carried on chiefly in Lombardy, employs 110,000 persons. The most considerable manufactures in metal are in Styria, Carinthia, and Lower Austria. The estimate of the annual products of the Austrian manufactures, given by Crome, is too extravagant to derive any credit. But those of Bohemia, in 1811, were valued at 158,000,000 of florins, and if we add twice as much for all the other states, the whole produce of the Austrian manufactures may, on this ground, be computed at L.47,000,000 Sterling. Even this is probably above the truth. (Lichtenstern, p. 44. Crome, 173-176.)

The commerce of Austria is extremely trifling. She possesses but a small extent of sea-coast, which is remote from the centre of her territories, is destitute of navigable rivers, and rendered difficult of access by mountains. The numerous rivers that water her dominions afford few advantages to her trade, as (excepting in Italy) she does not command the outlet of any one of them. The whole exports of this large empire are only L.3,000,000, and the imports L.3,200,000. (Lichtenstern, p. 48.)

---

* Lichtenstern, *Handbuch, der Neust Geog. des Oest.* 1818, p. 33—42. Crome, *Allg. Ubersicht*, 1818, p. 141-154; Mentelle et Malte-Brun, IV. 419.

The population of the Austrian empire, in 1817, was 28,207,886, of which the Sclavonic race amounted to 13,182,000, the Germans to 5,342,000, the Italians to 4,226,000, the Magyars, or Hungarians, to 4,225,000, the Wallachians to 1,246,000, and the Jews to 487,000. (Lichtenstern, p. 1858.) There are besides considerable numbers of Greeks, Turks, Albanians, and Armenians, so that, except Russia, no state in Europe has such a heterogeneous population. Throughout the Austrian dominions the nobility and clergy are numerous, and many of them very rich. In Hungary, Galicia, and indeed in the greater part of the empire, these classes are exempt from taxes, and enjoy other pernicious privileges. The Austrian clergy, exclusive of their families, are estimated at 64,000, of whom 56,000 belong to the Catholic church; the nobles of both sexes at 475,000, the civil servants of the government, with their families, at 280,000; the military, men, women, children, and servants, at 800,000; the burghers and tradesmen, with their families, at 2,333,000; the persons engaged in agriculture at 4,005,000 families, or about 20,025,000 individuals. (Lichtenstern, p. 133.) In all the provinces, especially in Bohemia, Moravia, and Hungary, there has been a rapid increase in the numbers of the inhabitants. Though the people are poor and ignorant, the government has been at much pains to provide them with the means of instruction; and the numerous schools and academies established, must essentially contribute to the improvement of the country. The Catholic religion, though it predominates, nowhere enjoys that exclusive ascendancy which produces such pernicious consequences in Spain and Italy. The other sects, Greeks, Calvinists, Lutherans, form nearly one-third of the inhabitants in the provinces beyond the Alps; and this circumstance, by generating a certain freedom of thought and discussion, must prove favourable to the progress of society.

Acquisitions and Losses of Austria from the Commencement of the French Revolution to the Year 1815.

Austria, in 1787, 240,000 square miles, 20,000,000 inhabitants. (Zimmermann's *State of Europe*, p. 150.)

	Square Miles.	Inhabitants.
Gained 1795, In Poland, .	17,500	1,100,000
1797, The Venetian territories east of the Adige,	13,450	2,023,000
1802-4, Trent, Brixen, Lindau, and other small territories, . .	4,800	290,000
	35,750	3,413,000
Lost ——, The Netherlands,	10,100	2,150,000
The Milanese, .	4,100	1,320,000
The Brisgau, .	1,150	140,000
	15,350	3,610,000
Absolute gain of territory, and loss of population, . .	20,400	197,000
Peace of Presburg, 1805.		
Lost Venetian territories,	13,450	2,023,000
The Tirol, Burgau, Eichtadt, Passau, Lindau, Rottenfels, and other small territories ceded to Bavaria, and seven towns to Wirtemberg,	11,000	815,000
	24,450	2,838,000
Gained Salzburg and Bertholsgaden, . .	3,610	202,000
Absolute loss, . .	20,840	2,636,000
Peace of Vienna, 1809.		
Lost Salzburg and Bertholsgaden,	3,610	202,000
Part of Inviertiel and Hausruck in Upper Austria, ceded to Bavaria, .	1,900	224,000
Carniola, two-thirds of Carinthia, Goritia, Dalmatia, and part of Croatia, ceded to France,	14,600	1,065,000
In Poland, Wester Galicia, the circle of Zamosc, and the district of Tarnopol,	25,000	1,904,000
	45,100	3,395,000

Austria, in 1809, 205,000 square miles, and 20,435,000 inhabitants (Marcel. de Serres, *Voyage* I. 40.)

Gained 1814-15, Salzburg, Tirol, Carniola, and other districts in Austria, formerly ceded with Dalmatia, Croatia, &c.	30,100	2,140,000
Poland, district of Tarnopol,	3,900	400,000
Venetian territories and Milan,	17,000	3,959,000
	*51,000	6,499,000

Austria, in 1818, 258,000 square miles, and 28,207,882 inhabitants. (Lichtenstern, p. 8. 1858.)

Prussia.

Prussia is the smallest in extent, and enjoys the fewest natural advantages of all the European states of the first class. Her territory is not much more than two-fifths of that of Austria; it is but indifferently fertile; has few valuable mines; few resources for manufactures; she has, however, pretty large extent of sea-coast, and a considerable commerce. Her possessions are straggling and disjointed; they present an extensive frontier, with little depth, and no natural barriers; and are inhabited by people who speak different languages, and have few common ties or interests. Prussia has sustained her rank chiefly in consequence of the superiority of her internal organization. Her government, unlike those of the other monarchies of Europe, being of very recent origin, is not encumbered by those ancient establishments which the change of circumstances has converted into abuses. The frame of her public institutions was improved and completed by the Great Frederick, who availed himself of all the lights and philosophy which the age furnished. He established a complete toleration in matters of religion; curtailed the oppressive privileges of the nobles; simplified the administration of justice; and introduced order and economy into every department of the government. He left the kingdom to his successor with a large and well disciplined army, and a high reputation for policy and prowess. The population of Prussia, of whom two-thirds are Protestants, is more intelligent than that of Austria, includes a greater proportion of Germans; and altogether she is more of a German power. The large rivers that water her territories have generally a very level course, and being joined by canals, they afford a great extent of inland navigation. Of all the old provinces, Silesia is the most industrious and flourishing. It doubled its population in the 73 years between 1742 and 1815.[*] The Westphalian and Rhenish provinces are the most populous; ancient Prussia and the Polish provinces the least. In many parts of Prussia vassalage existed lately, and perhaps still exists. It was only subsequent to the disasters of 1807, that the nobles, who amounted, in 1802, to 20,000 families, lost their monopoly of military offices of rank, and the right of holding property exempted from public burdens; and since that period also the restrictions on industry in towns have been done away by the abolition of corporation privileges. (Crome, 417; *MS. Travels in Germany.)*

* Hoeck, *Apercu*; Marcel. de Serres, *Voyage en Autriche* 1814; Hassel, *Allg. Europ. Staat*; Mentelle et Malte-Brun, *Geog. et Atlas.*

Agriculture remains in a low state in Prussia, in consequence of the ignorance and depressed state of the peasantry, the small size of the farms, the deficiency of capital, and the want of markets for the surplus produce. Besides the common species of grain, tobacco, mulberries, vines, flax, and hemp, are cultivated. Great quantities of potatoes are also raised. Horned cattle and sheep are pretty numerous in most of the provinces. M. Krug estimates the mean rent of an arpent of corn land, for the whole Prussian states, at $2\frac{1}{12}$ rix-dollars (about 7s.), and the *net produce* of an arpent of corn land at two-fifths of the gross produce; but of pasture land at one-fourth or one-fifth only, including poultry and bees.[†] According to returns made from the different provinces to the government, the whole annual produce of grain in Prussia about 1802, when the population was 8,754,000, was 4,500,000 *Wispel* (equal to 9,600,000 quarters); of which wheat formed 9 parts in the 100, rye 40, barley 24, and oats 27; of this quantity one-tenth was exported. The Prussian silver mines yield annually about 20,000 mark of silver; the county of Manifield alone furnishes 14,588 centners of copper; and Silesia affords 7600 centners of lead, and 405,900 centners of iron. The whole mineral produce of Prussia is valued at L.1,800,000 annually. (Mentelle et Malte-Brun, IV. 428; Crome, 400.)

The principal manufactures of Prussia are linen, woollen, cotton, silk, leather, iron, and porcelain, all of which are making progress. The linen, of which the chief seat is in Silesia, is the most considerable, and, as far back as 1804, was computed to produce yearly L.2,500,000 Sterling. The produce of the woollen manufactures, in 1805, was estimated at L.900,000; that of leather at L.600,000. The whole produce of manufactures, including breweries, we find stated, in 1802, at 41,000,000 of rix-dollars, or nearly L.7,000,000, Sterling. Considering the extension of the kingdom, and the progress of domestic improvement, it must now be at least double Of the commerce of Prussia we have no precise account for any recent period; but, in 1804, the imports of Silesia alone amounted to L.1,900,000, and the exports to L.2,100,000, exclusive of a transient trade valued at L.700,000; and in the same year, the imports of six provinces amounted to L.4,585,000. Supposing the trade of the other five provinces, of which the kingdom now consists, to be in proportion, and allowing for the advancing state of the country, we cannot estimate the whole imports at less than L.8,000,000 or L.9,000,000 Sterling, and the exports at as much. In 1802 the exports were stated at L.7,000,000 Sterling, by Malte-Brun.[‡]

The public revenue of Prussia in 1817, according to Demian, was 42,000,000 dollars, or about L.7,000,000.[§] After the great loss of territory in 1807, it was only L.2,700,000. The public debt in 1815, including that of the new provinces, was estimated at L.40,000,000. The army is about 175,000 men, exclusive of the landwehr.[‖]

In proportion as the other great states of Europe improve their natural resources, the importance of Prussia must decline. The time is past when the good order of her finances, and the discipline of her armies, could raise her to an equality with France and Austria and Russia; and she can only now support her rank by cultivating still farther those moral advantages which were formerly the source of her strength. It is the king's interest to give his subjects a free constitution and a free press, for which they are better prepared than those of any other great power on the Continent, except France. This would give a new impulse to industry, and create a spirit of improvement, which would more than counterbalance the natural disadvantages of the soil and climate. Were the king to enter cordially into the new opinions which are rapidly spreading over Germany, and to put himself at the head of those who support them, in the present temper of men's minds, it is probable he might unite a great part of northern Germany under his sway.

Acquisitions and Losses of Prussia since the commencement of the French Revolution.

	Square Miles.	Inhabitants.
1791, Gained Principalities of Anspach and Bayreuth,	3,500	420,000
1793, do. in Poland, 2d Partition, . . .	22,500	1,136,000
1795, do. do. 3d do.	16,500	860,000
1802, Received part of the German indemnities, and gave up possessions on the left bank of the Rhine, balance in favour of Prussia, . .	3,600	420,000
	46,100	2,836,000
Prussia in 1803, 116,000 sqr. miles, and 9,100,000. (Mentelle et Malte-Brun, IV. 202 and 428.)		
1806, Prussia took possession of Hanover, but was dispossessed by the French a few months after.		
1806-7, Lost all her possessions between the Elbe and the Rhine, with Anspach and Bayreuth, Cottbus in Saxony, Neufchatel, and four-fifths of her Polish territories.	56,500	4,450,000
Prussia in 1808, 59,600 square miles, and 4,559,550 inhabitants. (Hassel, *Europ. Staats*, I. 68.)		
1814-15, Recovered a part of her losses in Poland, and all her possessions in Saxony and Westphalia, with great additions, and made some exchanges. Total gain of territory and population, . .	44,600	5,506,000
Absolute gains of Prussia in each province.		
In Poland, in 1793 and 1795,	39,000	1,996,000
Add gained in 1772 at 1st partition. . .	12,000	600,000
	51,000	2,596,000
Lost in 1807, and not recovered in 1814, . . .	27,000	1,575,000
Still retains,	24,000	1,703,000
Brought forward,	24,000	1,703,000
(The population of the Polish provinces appears to have increased one-fourth since their first conquest.)		
In Saxony. Gained in the Duchy of Saxony, in Lusatia, Merseburg, Eichfield (part), Erfurt, and some towns, . .	7,800	920,000
In Westphalia and on the Rhine. Munster (three-fifths), Paderborn, Mark, Berg, Juliers, Electorate of Treves (four-fifths), Cologne, Duchy of Westphalia. Ceded East Frisia, Lingen, Hildsheim, ...	14,200	2,050,000
In Pomerania. Swedish Pomerania, ...	1,480	120,000
	47,480	4,793,000

Prussia, in 1815, 105,800 square miles, and 10,315,000 inhabitants. (Demian, *Geog. Preuss.*) In 1817, 10,588,157 inhabitants. *(Public Journals.)*

RUSSIA.

Russia occupies very nearly one-half of the surface of Europe, and yet her territories in this division of the globe are scarcely more than one-fifth of her whole dominions. Three-fourths of her Asiatic territories, however, consist of sandy deserts, or frozen plains, which yield very little for human subsistence; and her possessions in Europe are at present, and perhaps will always be, the most valuable part of the empire. European Russia consists chiefly of an elevated plain, over which numerous rivers flow with a small declivity, so as to afford a greater extent of inland navigation, probably, than exists in all the rest of Europe. Its superficial extent, including Poland, is about 1,687,000 square English miles, which is more than eight times the area of France, or fourteen times that of the British Isles. But of this surface more than one-fourth part, lying beyond the parallel of 60° is incapable of cultivation, from the rigour of the climate, or the marshy nature of the soil. In the south, also, there are vast sandy plains, the soil of which, destitute of wood and water, and impregnated with salt, is altogether useless for agriculture. The fertile part of Russia consists chiefly of the country lying between the parallels of 50° and 57°, which contains a great proportion of excellent soil, well watered with navigable streams, and comparatively populous and cultivated. The cultivation of wheat is chiefly confined to this region, and here abundant crops are procured with little labour, and by a very rude species of culture. But farther north, slender crops are obtained with so much exertion, that a single peasant cannot cultivate more than from seven to ten acres; and these crops are so precarious, that the rye sometimes will not ripen in the neighbourhood of Petersburg. The lands, however, where corn will not grow, yield pasture and wood. Trees are found as far as the 67th degree, beyond which there are only shrubs.*

It has been computed, that the soil incapable of cultivation in European Russia amounts to 690,000 square English miles, or 40 parts in the 100 of the whole surface. (Mentelle et Malte-Brun, II. 69.) The annual produce of corn in all Russia has been estimated at 181,000,000 tchetverts, including seed, equal to 126,000,000 quarters, and valued at 371,000,000 of rubles. But this estimate is evidently a gross exaggeration. The crown forests are estimated at 44,500,000 of desiatines, equal to 240,000 square miles. Rye is the grain most extensively cultivated all over Russia; but barley, wheat, and oats, are also raised. In the southern provinces, maize, rice, vines, and even cotton succeed; and both in the southern and central parts, vast ranges of pasture ground support numerous herds of cattle, the skins and tallow of which, with the peltries of wild animals, are leading articles of exportation. These pastures are generally commons: the quantity of uncultivated lands, says Storch, is so great, that it would be useless to divide them. The number of sheep in Russia has been estimated at 60,000,000. Flax and hemp, however, are the productions in which the soil of Russia has the greatest superiority, and of these she exports great quantities. Some of the less civilized nations are almost supported by bees, and wax and honey are also among the principal articles of exportation. The annual produce of raw silk in Russia is estimated at 10,000 pounds. Russia has rich mines of gold, silver, copper, iron, lead, and salt, the best of which are in the Uralian mountains, and chiefly on the Asiatic side. They employ about half a million of persons. Their annual produce is valued at 17,147,000 silver rubles, of which the crown receives 6,463,535 rubles. It consists of 1600 pounds of gold, 52,000 pounds of silver, 81,000 centner of copper, 18,181 centner of lead, and 6,224,692 centner of iron. The salt mines yield 8,000,000 centner of salt annually. The fisheries are supposed to employ a capital of 6,657,000 rubles, and to yield an annual gain of 2,200,000. (Crome, p. 58, 64, 67.)

The manufactures of Russia are inconsiderable, though the government has made great exertions to encourage this species of industry. The principal are those of coarse woollens, flax, iron, leather, silk, glass, and brandies. The manufacturing establishments, in 1812, amounted to 2331, and employed from 600,000 to 700,000 persons. In 1815 the number was 3262, of which 181 were for cloth, 150 silk, 1348 leather, 247 soap, tallow, and wax, 184 linen, 295 cotton, 138 glass, 200 metal. (Crome, p. 70.)

The exports of Russia, in 1796, including the goods carried out by land, and by the Caspian Sea, which do not appear in the customhouse returns, were estimated at 50,000,000 of rubles (Storch. II. 421); which is equal to L.8,330,000, if the silver ruble is meant; or L.5,870,000, if the paper ruble. In 1805, the exports were 72,400,000 rubles. The number of merchants was estimated at 97,227, and their trading capital at 308,000,000 rubles. The internal traffic between China, Siberia, and Moscow, employs 38,000 persons as carriers. (Crome, p. 73.)

If confidence might be put in the lists transmitted to government, the annual mortality in Russia is only 1 in 58, the births 1 in 26, and the annual addition to the population 1 in 49, so that the period of doubling should be 35 years. (Storch, I. 282.) But these extraordinary results are irreconcileable with facts. The population in 1783, according to Storch, was 27,397,000; and the highest estimates only make it amount to 42,722,000 in 1815, excluding the kingdom of Poland. (Hassel, p. 223.) Deducting about 6,000,000, added to the empire by conquest, the real increase, in 32 years, is only 9,425,000; and the period of doubling, calculated on this basis, would be 75 years, a rate of increase not greater than was exemplified in Silesia, and in Britain during the last 40 years. Russia, however, has ample room to allow her population to expand, as her soil in Europe would easily support 100,000,000; while the increase in other countries must be confined within narrow limits. There are in Russia above 80 nations, who speak more than 40 different languages; but the Sclavonic race forms seven-eighths of the whole European population. According to the official returns in 1783, the peasants, belonging to the crown and to the nobles, amounted to 83 persons in the 100 of the whole population. (Storch, I. 249.) Of the 45,500,000 of inhabitants, the Sclavonic race forms 38,000,000, the Finns 2,376,000, the Tartars 1,850,000, the Caucasian tribes 1,200,000, Monguls 300,000, colonists, including Moldavians, French, Germans, &c. 800,000. About one-ninth of the people live in towns. (Hassel, p. 223; Crome, p. 61.) The army, in 1815, amounted to 621,155; the navy to 32 ships of the line, and 18 frigates; the revenue is about L.25,000,000 Sterling. The public debt at the end of the war was about 600,000,000 rubles; the greater part, however, paper money. (Crome, 78, 80; Hassel, 226.) Of all the powers of Europe, Russia is the only one that, during the numerous changes of the last thirty years, has never lost any part of her territories; but has been continually adding to them. Her acquisitions since 1770 are as follows:

	Square Miles.	Population.
1772, First partition of Poland,	33,000	1,226,000
1793, Second do. do.	90,000	3,745,000
1795, Third do. do.	42,000	1,407,000
1774 to 1791, From the Porte,	60,000	204,000
1807, District of Bialystock, from Prussia, . .	4,200	183,000
1809, District of Tarnopol, ceded by Austria, containing 400,000 inhabitants, but restored in 1815.		
1809, Finland and Lapmark from Sweden,	120,000	895,000
1811, Part of Moldavia and Bessarabia from the Porte, .	13,000	230,000
1814, Duchy of Warsaw,† now the kingdom of Poland,	47,400	2,793,000
Total acquisitions of Russia since 1770 in Europe, . .	409,600	10,683,000

---

* Storch, *Tableau*, I. 4; II. 209, 229, 231; Crome *Ubersicht*, 55.

† Under the French rule, the Duchy of Warsaw included Posen, and part of the district of Netz, making

SWEDEN.

Sweden has sunk in her relative importance in consequence of the rise of Russia, but she still holds a higher place in the scale of power than any other European state with an equal population. Now that Norway is united to her dominions, she has the best military and commercial position of all the northern continental powers. But the soil is poor and rocky, so that, though her territories form one-tenth of the surface of Europe, her population amounts to less than one-fiftieth. Her principal wealth consists in her rich mines of iron and copper, and in the produce of her forests, and her fisheries.

The agricultural produce of Sweden, which does not suffice for her own consumption, consists chiefly of rye, oats, barley, and potatoes; the soil and climate not admitting of wheat, except in the southern parts. Gothland, the most fertile province, contains one-half of the population upon less than one-fifth of the surface of the kingdom, The soil actually in cultivation in Sweden in 1810 amounted only to 1,091,000 tunnas, or 1,363,838 acres; but the soil capable of cultivation was estimated at 1,818,450 acres, or one sixty-second part of the surface of the country. This is the average of the whole: but in the province of Norland only 1 acre in 915 is arable. The lakes cover one eighteenth part. The pasture ground and gardens occupy about twice the quantity of land under corn. The average size of a farm is only about 27 acres. The whole annual produce of grain is estimated at 5,702,835 spans, equal to about 1,482,500 quarters, besides 350,000 quarters of potatoes. The general produce of the crops is about 5 for 1. In Norway, the land in cultivation amounts to less than 1 acre in 100, and one-fourth of the grain used is imported. Potatoes are extensively cultivated. In times of scarcity bread is made of the bark of trees, and of the Iceland moss, on which the Reindeer feed. There were in Sweden, in 1810, about 403,700 horses, 1,475,700 black cattle of all kinds, and 1,212,700 sheep. The quantity of bar-iron manufactured in Sweden, in 1809, was 1,293,400 hundred weight, or 61,467 tons. This article forms seven-eighths of the whole Swedish exports. The annual produce of copper is 7546 skippund, or about 1000 tons; of lead, 14 tons; silver, 2730 marks; of gold, 10 marks. The mines employ about 50,000 persons. Of 24 counties, the 13 which abound most in forests contain 103,000 square English miles of woodland, while the annual consumption for all purposes in Sweden is computed to require only 2600 square miles. Sweden exports wood to the value of 900,000 dollars, and Norway to the value of 5,000,000 dollars yearly. (Crome, 98, 102, 119. Thomson's *Travels*, 392—431.)

The manufactures of Sweden are of little importance. Sixty or seventy ships are built annually and sold to foreigners. The distillation of brandy consumes 700,000 spans of corn a-year. The manufactures of paper and glass and works in metal supply the internal consumption; those of cotton, wool, and silk, are of small extent. The whole produce of manufactures in Sweden (exclusive of Norway), in 1814, was valued, in an official statement, at 5,622,129 dollars banco, or about L.800,000. (Crome, 123.)

The exports of Sweden, in 1816, were estimated at seven millions of dollars (exclusive of Norway), and the imports at no less than twenty millions. The supposed national loss arising from this disproportion, led to a prohibition of the importation of wine, rum, cotton, stuffs, and other articles considered as luxuries. In 1816, Sweden had 1107 merchant ships, amounting to more than 64,000 lasts, or 120,000 tons of tonnage. (Crome, 122, 125.)

The population of Sweden was estimated at 2,615,800 in 1818; that of Norway, in 1803, was 910,000, and from the probable rate of increase there, may now amount to nearly one million. In Sweden about one-ninth, and in Norway about one-twelfth of the people live in towns. This increase in numbers has been attended with an improvement in the condition of the inhabitants. The annual mortality in Sweden, which Malthus, in 1796, estimated at 1 in 37, was, in 1811, according to Akrell, 1 in 40 for the southern parts, 1 in 47 for the northern, and 1 in 43 for the whole kingdom. In Norway the mortality has always been smaller than in any other European country. In 1815 the nobles amounted to 1641 families, or 9523 persons, the clergy, including their families, to 15,202, the burghers to 64,755, and the peasants to 1,763,397. Besides these classes, who are represented in the diet, there are about 500,000 persons not represented, consisting of civil and military officers, miners, mechanics, servants, &c, 153,797, or about one-fourth of the peasants who are householders, farm their own lands. The established religion is Lutheran, and the number of parochial clergyman in Sweden is 1094, besides 170 prebends, 11 bishops, and 1 archbishop; and the tithes amount to 283,232 spans, or about 72,500 quarters of corn. Norway has 467 clergymen, including 5 bishops. (Crome, 96, 116. Thomson's *Travels*, 418.)

Subsequent to the revolution in 1809, some improvements have been made in the constitution, by enlarging the powers of the diet. The four estates of nobles, clergy, burghers, and peasants, who sit in separate houses, meet necessarily at the end of five years, or oftener if convoked by the king. The consent of three of these houses, with that of the king, gives a proposition the force of law. No taxes can be raised without the authority of the diet, and the persons of the members are inviolable during the session. The conscription, which was introduced in 1809, subjects all males between 20 and 25 to military service; and the nobles have been deprived of the exemption they formerly enjoyed from this service and from taxes. The press is declared by the constitution to be free, but is in fact under the control of the police. The revenue of Sweden and Norway

---

its extent 65,000 square miles, and its population 3,800,000. The total acquisitions of Russia in Poland amount to about four-fifths of the country, and three-fourths of the population. (Hassel, *Allg. Europ. Staats*, Mentelle et Malte-Brun, *Geog. et Atlas*; Storch, *Tableau.*)

is about L.1,500,000. The debt of Sweden, in 1816, was 10,209,611 dollars banco, or about L.1,480,000, and Norway also owes a considerable sum. The army for both countries, in 1817, consisted of 53,560 men: the navy about 20 ships of the line, and 16 frigates. (Crome, p. 131–137. James's *Travels*, I. 281.)

The acquisitions and losses of Sweden, since 1789, may be stated thus:

	Square Miles.	Inhabitants.
1809, Lost Finland and Lapmark, conquered by Russia, .	120,000	895,000
Pomerania, .	1,480	120,000
	121,480	1,015,000
1813, Acquired Norway by cession from Denmark, .	148,000	950,000
Absolute gain of territory and loss of population, . .	26,520	65,000

SPAIN.

The vast natural resources of this country present a striking contrast with its political imbecility. It is nearly as large as France, but contains little more than a third of the population, though its fertile soil and delicious climate yield in abundance the productions both of the temperate and warm regions of the globe. With its great extent of sea-coast, numerous rivers, and excellent position for trade, and its rich and extensive colonies, nothing but extreme misgovernment could have prevented it from becoming the first commercial city in the world.

In addition to silk, tobacco, vines, olives, and all the agricultural productions of France and Germany, Spain produces the orange, citron, sugar-cane, cork tree, dates, figs, and cotton. Wheat is the grain most extensively cultivated. Barley and rye are next in quantity. Very few oats or potatoes are raised, but considerable quantities of maize and rice. Hemp to the value of a million of piastres is raised yearly; and flax is cultivated on a smaller scale. The vineyards, besides supplying the internal consumption, furnish 3,000,000 or 4,000,000, or, according to other accounts, 10,000,000 or 11,000,000 gallons of wine for exportation, and half as much brandy. Olive oil is exported to the value of L 600,000 a-year. The annual produce of raw silk is valued at L.300,000. But wool is the produce for which Spain is most celebrated. The number of merinos or migratory sheep, which furnish the finest wool, is estimated at 5,000,000; those that are stationary at 8,000,000; and these 13,000,000 of sheep are supposed to afford yearly 45,000,000 of pounds of wool. The right of pasture which the migratory flocks have over whole provinces, is one great obstacle to agricultural improvement. From this and other causes, one-third or one-half of the kingdom is left entirely waste, and the part in cultivation is wretchedly managed. Nearly the whole land in the kingdom is locked up by entails in the hands of the nobles and the clergy, and the small portions brought into the market sell so high as not to afford more than one and a half *per cent*. upon their price. Agriculture is entirely in the hands of the peasantry, who are poor and ignorant; men of capital never engage in it; and the grandees, who should support and encourage improvements, all reside in the large towns. In the whole of Spain, there is scarcely to be seen a villa or gentleman's seat, except a few that are in ruins. The mines of Spain, like her agriculture, are neglected; but she still derives from her own soil a considerable supply of iron, copper, lead, and mercury. About 5,000,000 centners of salt are annually obtained from mines, springs, or the sea.*

The greatest number of the Spanish manufactures are in Catalonia, but a few are scattered through the other provinces. The most considerable are the woollen, silk, linen, cotton, hemp, leather, paper, and metal, but none of them are sufficient for the internal consumption of the country, and all of them are fettered by vexatious taxes, absurd regulations, and the difficulty of intercourse between the provinces. The manufacture of tobacco is a royal monopoly. (Laborde, IV. 320.)

We have no accurate accounts of the commerce of Spain for a recent period. The exports in 1788 were L 6,951,000, of which rather more than the half went to America. (Laborde, IV. 410.) In 1802, the exports were estimated by Malte-Brun at 240,000,000 francs, or nearly L.10,000,000 Sterling. (Mentelle et Malte-Brun, *Geog.* II. 31.)

It is now pretty well ascertained, that the apparent decline of Spain has been the consequence of the rapid progress of her neighbours; and that, down to the end of the eighteenth century, she was advancing both in industry and population. From a combination of circumstances, the causes which check the progress of society have operated more powerfully there than in any other country of Europe except Turkey. Among the greatest evils in the state of the country may be reckoned the excessive number of the nobility and clergy, with their oppressive privileges, and their pernicious influence upon the other classes. In 1788, when the population amounted to 10,500,000, the number of the secular and regular clergy was 147,722, of the nobles 478,716, of peasants and labourers 1,847,010, of manufacturers and handicrafts 302,000, servants 276,090, merchants 34,030. The Spanish army, in 1806, consisted of 153,840 men in Europe, and 129,053 in America; the navy consisted of 42 ships of the line, and 30 frigates. In 1804, the revenue, according to Humboldt, was 43,000,000 piastres, or L 9,150,000. In the Budget for 1818, it is estimated at L.8,248,000, and the expenditure at L.9,611,000. The debt in 1809 was stated to amount to L 43,100,000, and in 1817 to L.127,852,000 †

GERMANY.

In the early part of the eighteenth century, Germany consisted of about 300 Sovereign States, great and small, which were united into one empire by

a very complicated constitution. From time to time some of the smaller principalities have been suppressed and incorporated with the larger states; but the first radical change in the composition of the Germanic body was made by the treaty of Luneville, 9th February 1801, when a vast number of bishoprics, abbeys, and free towns, were deprived of their rights of sovereignty, and given as indemnities to princes who had lost their possessions in Belgium and Italy by the French conquests. In 1806, the Emperor Francis formally renounced the dignity of head of the empire; the ancient constitution of the empire was dissolved, and a new league formed with France at its head (see CONFEDERATION OF THE RHINE), comprehending the most considerable states in the south, to which those in the north were afterwards added. This confederation fell to pieces on the overthrow of the French power in 1813, but it has served as the foundation of the new constitution of the Germanic body. The number of states is now reduced to 39, including Austria, Prussia, Denmark, and the Netherlands; but these four powers rank as members only for a part of their dominions. The ecclesiastical principalities are entirely abolished; and the free towns, of which there were 47 or more in 1800 (Hoeck's *Tables*), are now reduced to four. The princes who have lost their sovereignty have been reduced to the rank of nobles, and no longer holding immediately of the empire, are said to be *mediatised*. The titles of royalty conferred by Bonaparte upon Bavaria, Wirtemberg, and Saxony, have been confirmed, and Hanover has since been raised to the same rank. The common concerns of this confederacy are managed by a diet, consisting of deputies from thirty-eight states (Hesse Homberg having no vote), who meet at Frankfort. The pecuniary contributions, fixed in proportion to the population of each state, are voted for a period of five years. The military contingents, which are regulated on the same principle, amount to 120,000 men in time of peace, and 301,000, in time of war, the latter being at the rate of 1 in the 100 of the population. The German states, including $\frac{3}{7}$ths of Austria, $\frac{4}{7}$ths of Prussia, besides Holstein and Luxemburg, embrace an era of about 237,000 English square miles, with 30,095,050 inhabitants; of whom about 15,500,000 are Catholics; 12,000,000 Lutherans; 2,100,000 Reformed; 25,000 Moravians; 14,000 Greeks; and 182,000 Jews. The new Germanic constitution, though less complicated than the old, can scarcely be expected to produce any of the effects of a solid union in such a heterogeneous mass. The states are too unequal in strength to have a proper reciprocal influence, and there is not weight enough in the minor members to control the rival interests and jealousies of Austria and Prussia. The confederation may be considered as recognizing, and in some degree regulating, the influence which the greatest states must necessarily exercise indirectly over the smaller. (Hassel, I. 17. *Public Journals.*)

The following Table exhibits the result of the various changes since the commencement of the French Revolution, upon the principal members of the Confederation; but to enter into particulars would carry us beyond the proper limits of this article. Most of them (except Saxony) have been enriched by the breaking up of the ecclesiastical principalities.

	Before the Revolution.		In 1816.	
	Square Miles.	Population.	Square Miles.	Population.
Bavaria, .	22,000	2,183,000	30,000	3,560,000
Saxony, .	14,800	2,104,000	7,200	1,200,000
Hanover, .	10,900	787,000	14,400	1,305,000
Wirtemberg,	3,200	608,000	8,200	1,395,463
Baden, .	1,370	177,000	5,800	1,001,700
Hesse Cassel,	3,340	443,500	4,300	540,000
Hesse Darmstadt,	2,180	249,700	4,100	619,500
Oldenburgh, .	960	95,000	2,500	217,000

(Hoeck, *Apercu.*—Hassel, *Europ. Staats*, 1816.)

Since the Congress of Vienna, many political changes of much importance have taken place in Germany; and, from the state of the public mind, it is evident that many more are in progress; but it does not belong to the objects of the present article to enter upon these subjects.

Smaller States.

The most important details regarding the *smaller states* will be found in the subjoined Table, which exhibits a view of the extent, population, revenue, military force, and religion, of all the sovereign states of Europe.

With respect to the authorities for this Table we may mention generally, that the extent assigned to Russia was ascertained, by measurement, on Arrowsmith's Map, and the other numerical statements respecting that country are taken from Hassel and Crome. All those relating to Austria are taken from Lichtenstern; those relating to Prussia from Demian and Hassel; those relating to France from Chaptal, Hassel, and public Journals; those relating to Britain from Colquhoun, Sinclair, and Parliamentary documents, except the amount of the population, which is calculated on the basis of the returns in 1801 and 1811. Most of the others are from Hassel and Crome; except the statements of the population and military force of the small German States (No. 23), which are taken from a paper published by the Diet in 1818, fixing the military contingents of each state. These contingents are for a period of war, whereas the numbers given in the preceding part of the table represent the military peace establishments of the respective states. But as most of the German States keep up a greater number of troops than required by the act of the Diet, the numbers given in the table will not actually exceed the military force of these states in time of peace. (B. B. B.)

EXCHANGE.

In the science of Political Economy, the term Exchange is commonly understood to designate exclusively that species of mercantile transactions, whereby the debts of individuals, residing at a distance from each other, may be either partially or wholly liquidated, without the intervention of money. The object of this article is to explain the nature of these transactions, and the principles on which they are founded.

This will be best effected, by treating, *first*, of the exchange between different parts of the same country; and, *secondly*, of that between different and independent countries.

Inland Exchange.

Inland Exchange.

Suppose a merchant, residing in London, orders his agent in Glasgow to purchase a thousand pounds worth of cottons on his account; then, although it should not suit the Glasgow merchant to commission goods of equal value from his London correspondent, the latter may nevertheless be under no necessity of remitting cash to Glasgow to discharge his debt. Among cities, or countries, having a considerable intercourse together, the debts mutually due by each other are found, in ordinary cases, to be nearly equal. And, therefore, the Glasgow merchant, who has shipped the cottons for London, does not transmit the bill, drawn by him on his correspondent for their price, directly to London to be cashed, for that would subject him to the expence of conveying the money home from London to Glasgow, but he gets its value from *some other merchant in Glasgow*, who has payments to make in London, on account of teas, wines, &c. imported from that city, and who, unless he could procure such a bill, would be obliged to remit their price in money. The bill on account of the cottons is, therefore, either drawn in favour of the person to whom the money for the tea and wine is owing in London, or it is drawn in favour of the tea merchant in Glasgow, and indorsed to him; and this last person, by presenting the bill to the purchaser of the cottons, receives its value, and consequently the price of the cottons, and the price, or part of the price, of his tea and wine at the same moment. By this simple contrivance, therefore, the expence and risk attending the double transmission, first, of money from London to Glasgow to pay the cottons, and, second, of money from Glasgow to London to pay the teas and wines, is entirely avoided. The debtor in one place is changed for the debtor in the other; and both accounts are settled without the intervention of a single farthing.

Inland Exchange.

The bill drawn and negotiated in such a transaction as this, is termed an *inland* bill of exchange. If the transaction had taken place between London or Glasgow, and a foreign city, it would have been termed a *foreign* bill of exchange.

A bill of exchange may, therefore, be defined to be, "An order addressed to some person residing at a distance, directing him to pay a certain specified sum to the person in whose favour the bill is drawn, or his order."*

Circumstances which determine the Price of Inland Bills of Exchange.

The price of bills of exchange fluctuates according to the abundance or scarcity of them in the market, compared with the demand. Thus, to revert to our former example, if we suppose the debts reciprocally due by London and Glasgow to be equal, whether they amount to L.10,000, L.100,000, or any other sum, they may all be discharged without the agency of money, and the price of bills of exchange will be at par; that is, a sum of L.100 or L.1000 in Glasgow will purchase a bill for L.100 or L.1000 payable in London, and *vice versa*. But if these two cities are not mutually indebted in equal sums, then the price of bills of exchange will be increased in the city which has the greatest number of payments to make, and will be proportionably reduced in that which has the fewest. If Glasgow owes London L.100,000, while the debts due by London to Glasgow only amount to L.90,000, it is clear, inasmuch as the merchants of Glasgow have a larger sum to remit to London, than the merchants of London have to remit to Glasgow, that the price of bills on London would rise in Glasgow, because of the increased competition; and that the price of bills on Glasgow would fall in London, because of the proportionably diminished competition. And hence a larger sum would be required to discharge any given amount of debt due by Glasgow, and a less sum would be required to discharge a corresponding amount of debt due by London; or, which is the same thing, the exchange would be in *favour* of London, and *against* Glasgow. Bills on London would sell in Glasgow for a *premium*, and bills on Glasgow would sell in London at a *discount*, the amount of the premium in the one case, and of the discount in the other, being obviously equal.

On the supposition, that the balance of L.10,000, due by Glasgow, depressed the exchange of that city on London *one per cent.*, it would at first sight appear as if it would cost Glasgow L.101,000 to discharge its debt of L.100,000 due to London; and that, on the other hand, L.89,108 would be sufficient to discharge the debt of London to Glasgow. But a very little consideration will serve to show that this could not really be the case. No exchange transactions can take place between different cities, until there be both debtors and creditors of the one residing in the other. And hence, when the exchange became unfavourable to Glasgow, the premium paid by the Glasgow merchants for bills drawn on London would not go into the pockets of their creditors in that city, but into the pockets *of their neighbours in Glasgow, to whom London was indebted*, and from whom the bills had been purchased. The loss to Glasgow would, therefore, be limited to the *premium* paid on the balance of L.10,000. Thus supposing that A of Glasgow owes D of London L.100,000, and that C of London owes B of Glasgow L.90,000, A will pay to B L.91,000 for a bill, or order on C to pay D L.90,000. In this way, the L.90,000 London debt at Glasgow would be quite cleared off; the premium, which is lost by the debtor to London in Glasgow, being gained by its creditor in the same place. If the business had been transacted in London, C, with L.89,108, would have purchased of D a bill for L.90,000 payable by A, so that, in this case, the gain would have fallen to the share of the debtor C, and the loss to that of the creditor D, both of London. The complexity of real transactions does not affect the principles on which they are founded; and to whatever extent Glasgow might be indebted to London, or London to Glasgow, the only disadvantage under which either of them would in consequence be placed, would be the unavoidable one of paying the expence of remitting the *balance* of debt.

---

* In mercantile phraseology, the persons who draw a bill is termed the *drawer;* the person in whose favour it is drawn, the *remitter;* the person on whom it is drawn, the *drawee*, and after he has accepted, the *acceptor*. Those persons into whose hands the bill may have passed previous to its being paid, are, from their writing their names on the back, termed *indorsers;* and the person in whose possession the bill is at any given period, is termed the *holder* or *possessor*.

Natural limit to fluctuations in the Exchange.

The expence of transmitting money from one place to another forms the natural limit to fluctuations in the exchange. If 20s. sufficed to cover the expence and risk attending the transmission of L.100 from Glasgow to London, it would be indifferent to a Glasgow merchant, whether he paid one *per cent. premium* for a bill of exchange on London, or whether he remitted money direct to that city. If the premium was less than one *per cent.*, it would be clearly his interest rather to make his payments by means of bills of exchange than by remittances; and that it could not exceed one *per cent.* is obvious, for every individual would rather directly remit money, than incur an unnecessary expence, by purchasing a bill on London at a greater *premium* than would be sufficient to cover the expence attending a money remittance. If, owing to the badness of the roads, to disturbances in the country, or to any other cause, the expence of remitting money from Glasgow to London should be increased, the difference in the rate of exchange between these two cities *might* also be proportionably increased. But in every case, the extent to which this difference could attain, would necessarily be limited by, and could not, for any considerable period, exceed the cost of making remittances in cash.

Exchange transactions become more complex, when one place, as is very often the case, discharges its debts to another by means of bills drawn on a third place. Thus, although London should owe nothing to Glasgow, if Glasgow is indebted to London, London to Manchester, and Manchester to Glasgow; Glasgow would either wholly or partially discharge its debt to London by a bill drawn on Manchester. It would wholly discharge it, provided the debt due to Glasgow in Manchester was equivalent to the debt due by Glasgow to London. But if this be not the case, Glasgow must either remit money to London to discharge the *balance* of debt, or bills drawn on some other place indebted to her.

Transactions in inland bills of exchange are almost entirely conducted by bankers, who charge a certain rate *per cent.* for their trouble, and who, by having a credit in those places to which they are in the habit of remitting bills, are enabled, on all occasions, to supply the demands of their customers. In Great Britain, London, because of its intimate connection with other parts of the country, occasioned partly by its immense commerce, partly by its being the seat of government, and the place to which the revenue is remitted, and partly by its currency consisting of Bank of England paper, for which the paper currency of the country banks is rendered exchangeable, has become the great focus in which all the money transactions of the empire centre, and in which they are ultimately adjusted. In consequence of these various circumstances, but chiefly of the demand for bills on London to remit revenue, and of the superior value of Bank of England currency, the exchange between London and the other parts of the country is invariably in its favour. Bills on London drawn in Edinburgh and Glasgow were formerly made payable at 40 days' date, which is equivalent to a *premium* of about $\frac{1}{2}$ *per cent.*; but, owing to the greater facility of communication, this *premium* is now reduced to 20 days' interest, or to about $\frac{1}{4}$ *per cent.* Bills for remitting the revenue from Scotland are now drawn at 30 days; previously to summer 1819 they were drawn at 60 days.

What has been already stated is sufficient to show, that, however well fitted bills of exchange may be for facilitating the operations of commerce, and saving the trouble and expence attending the transportation of money, it is impossible to adjust mercantile transactions by their means, except in so far as the accounts mutually balance each other. A *real* bill of exchange is merely an order entitling the holder to receive payment of a debt *previously contracted* by the person on whom it is drawn. It is essential to the existence of such a bill that an equivalent amount of debt should first have been due. And hence, as the amount of the real bills of exchange drawn on any one merchant, or body of merchants, cannot exceed the amount of the debts due by them, if a greater sum is owing them than what they owe to others, the *balance*, it is obvious, must either be paid in money, or by the delivery of some sort of commodities possessed of real value. If, as in the example just given, Glasgow owes London L.100,000, while London only owes Glasgow L.90,000, a reciprocal transfer of debts may be made to the extent of L.90,000. But the Glasgow merchants cannot discharge the additional L.10,000 by means of bills drawn on London; for, by the supposition, London only owed them L.90,000, and they have already drawn for its amount. The balance, therefore, must either be discharged by an actual money payment, or by the delivery of some species of commodities, or by bills drawn on some third party who may be indebted to Glasgow.

Fictitious Bills of Exchange.

We do not mean by this to insinuate that there are no *fictitious* bills of exchange, or bills drawn on persons who are not really indebted to the drawer in the market. In every commercial country bills of this description are always to be met with; but they are only a device for obtaining loans, and do not and cannot transfer real debts. A merchant in London may form a connection with a merchant in Glasgow, and draw bills of exchange upon him payable a certain number of days after date, which the latter may retire by selling in Glasgow an equal amount of bills drawn upon his correspondent in London. The merchants who purchase, or the bankers who discount these bills, really advance their value to the drawers, who, as long as they continue, by means of this system of *drawing* and *redrawing*, to provide funds for their payment, continue in fact to command a borrowed capital equal to the amount of the fictitious paper in circulation. It is clear, however, that the negociation of such bills can have no effect in the way of transferring and settling the real *bona fide* debts reciprocally due between any two or more places. Fictitious bills mutually balance each other. Those drawn by London on Glasgow are exactly equal to those drawn by Glasgow on London, for the one set are drawn to pay the other—the second destroys the first, and the result is nothing.

The method of raising money by the discount, or, which is the same thing, by the sale of fictitious bills, has been severely censured by Dr Smith, as entailing a ruinous expence on those engaged in it, and as being resorted to only by projectors, or persons of suspicious credit. When fictitious bills are drawn at two months' date, there is, in addition to the ordinary interest of 5 *per cent.* a commission of about ½ *per cent.*, which must be paid every time the bill is discounted, or, at least, *six* times in the year. The total expence of money raised in this way could not, therefore, supposing the transaction to be always on account of the same individual, be estimated at less than 8 *per cent. per annum;* and the payment of so high a rate of interest on borrowed capital, in a country where the ordinary rate of mercantile profit is only supposed to average from *six* to *ten per cent.*, could not fail to be generally productive of ruin to the borrower. It seldom happens, however, that in transactions carried on by means of fictitious bills, the whole charge for commission falls on one individual. Loans obtained in this way are almost always on account of two or more persons. Thus, at one time a fictitious bill may be drawn by A of London on B of Glasgow; and, in this case, the Glasgow merchant will, before the bill becomes due, draw upon his London correspondent for the proceeds of the bill, including interest and commission. At another time, however, the transaction will be on account of B of Glasgow, who will then have to pay commission to his friend in London; so that each party may, on the whole, as Mr Thornton has observed, gain about as much as he pays in the shape of commission.

It is often extremely difficult to distinguish between a fictitious bill and one which has arisen out of a real mercantile transaction. Neither does it seem to be of any very material importance. The credit of the persons whose names are attached to the bills offered for discount, is the only real criterion by which either a private merchant or a banker can judge whether he ought to negotiate them. The circumstance of a merchant offering considerable quantities of accommodation paper for discount, ought, unquestionably, if discovered, to excite a suspicion of his credit. But unless in so far as the drawing of fictitious bills may be held to be indicative of overtrading, or of a deficiency of capital to carry on the business in which the party is engaged, there does not appear to be any good reason for refusing to discount them.

These few observations will, perhaps, suffice to explain the manner in which transactions between different parts of the same country are settled by means of bills of exchange. They are, in general, extremely simple. The uniform value of the currency of a particular country renders all comparison between the value of money at the place where the bill is drawn and negociated with its value where it is to be paid unnecessary; while the constant intercourse maintained between the different commercial cities of the same kingdom, by preventing those derangements to which the intercourse between distant and independent countries must always be subject, also prevents those sudden fluctuations which so frequently occur in the market price of foreign bills of exchange. We shall, therefore, leave this part of our subject, and proceed to investigate the circumstances which influence the course of exchange between different and independent countries.

FOREIGN EXCHANGE.

Foreign Exchange.

The price of Foreign bills of exchange depends entirely on two circumstances; *first*, on the value of the currency at the place where they are made payable, compared with the value of the currency at the place where they are drawn; and, *secondly*, on the relation which the supply of bills in the market bears to the demand.

If the real and nominal value of the currencies of the different nations having an intercourse together remained invariable, such fluctuations in the price of bills of exchange as arise from the first of these circumstances would be altogether unknown. But, as the comparative value of the pound Sterling, dollar, franc, guilder, florin, &c. is subject to perpetual variation, the price of bills of exchange must vary accordingly. Such variations, however, as proceed from this cause, affect merely their *nominal*, or rather numerical value. It is those only which arise from variations in the supply and demand for bills, or, which is the same thing, in the payments a country has to make compared with those it has to receive, that can be considered as *real*; and hence the distinctions of *nominal*, *real*, and *computed* exchange. The *first* depends on alterations in the relative value of the currencies to be compared together; the *second* depends on the supply of bills in the market compared with the demand; and the *third*, or *computed* exchange, depends on the combined effects of the other two. For the sake of perspicuity, we shall treat of these separately.*

SECTION I.—*Nominal Exchange.*

Nominal Exchange.

Bullion being every where recognized as the standard currency of the commercial world, the comparative value of the currencies of particular countries must depend, 1*st*, On the relative value of bullion in those countries; and, 2*dly*, On the *quantity* of bullion contained in their coins, or on the quantity of bullion for which their paper-money, or other circulating media will exchange.

Inquiry into the circumstances which regulate the value of Bullion in different Countries.

I. The real price of commodities being always proportionable not merely to the actual cost of their production, but also to the cost necessarily incurred in conveying them from where they have been produced to where they are to be made use of, it follows that, if the trade in the precious metals were perfectly free, and if the commodities produced in different countries were nearly all equally well fitted for exportation, the value of bullion in different countries would be chiefly regulated by their respective distances from the mines. Thus, on the supposition that neither England nor Poland had any other commodities except corn to exchange with the South Americans for bullion, it is evident that the precious metals would possess a greater value in Poland than in England, because of the greater expence of sending so bulky a commodity as corn, the more distant voyage, and because of the greater expence of conveying the gold to Poland. If Poland, however, had succeeded in carrying her manufactures to a higher pitch of improvement than England, her merchants might have been able, notwithstanding the disadvantage of distance, by exporting commodities possessed of great value in small bulk, and on which the expence of freight would have been comparatively trifling, to have sold bullion on cheaper terms than those of England. But if, as is actually the case, the advantages of skill and machinery were possessed by England, another reason would be added to that derived from her less distance from the mines, why gold and silver should be less valuable in England than in Poland, and why the money price of commodities should be higher in the former country. (Ricardo, *Principles of Political Economy, &c.* 1st Ed. p. 175.)

Hence, after nations have attained to different degrees of excellence in manufacturing industry, the value of bullion in different countries will no longer depend entirely on their distance from the mines. But, whatever variations a different progress in the arts may occasion in the value of bullion, as compared with particular commodities in different countries, it is certain that it must always be less valuable in those countries into which it is imported than in those in which it is produced. Bullion, like every other commodity, *is exported to find, not to destroy its level.* And, unless its value in Europe exceeded its value in America by a sum sufficient to cover the expences attending its importation, and to yield the ordinary rate of profit to the importer, we should not, although the mines of Mexico and Peru were a thousand times more productive than at this moment, be able to import a single ounce of bullion. It is obviously incorrect, therefore, to lay down as a general proposition, "that the *par* of exchange between two countries is that sum of the currency of either of the two, which, in point of intrinsic worth, is precisely equal to a given sum of the other, *that is, contains precisely an equal weight of gold and silver of the same fineness.*" (*Bullion Report*, p. 22, 8vo. edit.) For a given quantity of gold and silver is not always, as is here assumed, of the same intrinsic value in different countries. It may not, indeed, differ very materially among nations in the immediate vicinity of each other, and which are all destitute of mines. But although, to use a familiar illustration, the value of sugar approaches nearly to a level in the great trading cities of Europe, it cannot surely be maintained, that its value, in the West Indies, is the same with its value in Bourdeaux or Liverpool, or that the exchange would be at true *par*, if a bill, which cost 100 hogsheads of sugar in London, only brought 100 in Jamaica. Now, this is precisely the case with bullion. Though the value of gold and silver, as compared with corn, labour, &c. may, and indeed must, vary very considerably among the different European nations, these variations are only the necessary result of their different progress in industry, and of the different quality of their cultivated lands, &c. Such a difference of prices is the natural order of things; and bullion has only found its proper level when a sufficient quantity has been introduced into those countries which excel in manufactures, so as to raise the price of their corn and labour. These variations have, therefore, no effect on the exchange. An ounce of bullion in one country, notwithstanding this difference of price, will, because of the facility of intercourse, be very near equivalent to an ounce of bullion in another; and, supposing the trade in the precious metals to be perfectly free, the exchange will be at true *par* when bills are negociated on this footing. But when we compare the value of the precious metals in very distant countries, and especially in those in which they are produced with those into which they are imported, it is obvious that, considered merely with reference to the exchange, it must differ considerably. Gold and silver, like coal, tin, &c. must always be really cheaper in countries possessed of extraordinarily productive mines, than in those possessed of mines of a secondary degree of fertility, or in which they are entirely imported from abroad. And the exchange between such places can only be at true *par* when adequate allowance has been made for this difference of value. Thus, if, because of the expence of carriage, the value of bullion in Great Britain is 5 *per cent.* greater than in Rio Janeiro, 100 ounces of pure gold in Rio Janeiro would not be worth 100 ounces of pure gold in London, but 5 *per cent.* less; and the exchange would be at true *par* when bills for 105 ounces of standard bullion payable in Rio Janeiro, sold in London for 100 ounces.

---

* Supposing every country to be in possession of its proper supply of bullion, the exchange may be said to be *nominally* affected by the amount of the difference between the market and mint price of bullion, and to be *really* affected by any deviation from *par* exceeding or falling short of that difference.

The differences in the value of the precious metals in different countries, have not been confined to those which depend on their respective distances from the mines, or on their different progress in the arts. The opinion formerly so very prevalent, that gold and silver alone constituted real wealth, induced almost every commercial nation to fetter and restrict their exportation, and to adopt a variety of measures intended to facilitate their importation. But these regulations, even when most rigorously enforced, have been singularly ineffectual; the great value and small bulk of the precious metals, rendering it not only extremely advantageous, but also comparatively easy to smuggle them abroad, whenever their relative value declined.

"When," says Dr Smith, "the quantity of gold and silver imported into any country exceeds the effectual demand, no vigilance of government can prevent their exportation. All the sanguinary laws of Spain and Portugal are not able to keep their gold and silver at home. The continual importations from Peru and Brazil exceed the effectual demand of those countries, and sink the price of these metals *below* their price in the neighbouring countries. If, on the contrary, in any particular country their quantity fell short of the effectual demand, so as to raise their price *above* that of the neighbouring countries, the government would have no occasion to take any pains to import them. If it were even to take pains to prevent their importation, it would not be able to effect it. Those metals, when the Spartans had got wherewithal to purchase them, broke through all the barriers which the laws of Lycurgus opposed to their entrance into Lacedemon. All the sanguinary laws of the customs are not able to prevent the importation of teas of the Dutch and Gottenburgh East India Companies, because somewhat cheaper than those of the British Company. A pound of tea, however, is about an hundred times the bulk of one of the highest prices, 16s., that is commonly paid for it in silver, and more than two thousand times the bulk of the same price in gold, and is consequently just so many times more difficult to smuggle." (*Wealth of Nations*, Vol. II. p. 149.)

But, however ineffectual as a means of entirely preventing the egress of the precious metals, the restrictions on their exportation have nevertheless contributed to occasion some slight variations in their value in different countries. The risk incurred by the clandestine exporters of bullion from Spain is supposed to be equivalent to about 3 *per cent.*; or, which is the same thing, it is supposed, that the restrictions maintain such an excess of gold and silver in that country as to sink their value 3 *per cent.* below their value in those countries in which the trade in bullion is unrestricted. In calculating the true *par* of exchange between Spain and other countries, this circumstance must be taken into account. For, however much the value of bullion in one country may be reduced below its value in those with which it maintains an intercourse, the nominal exchange must necessarily be unfavourable to that extent.*

It results as a consequence of these principles, that whatever occasions a rise or fall in the relative value of the precious metals, in a particular country, must proportionably affect its nominal exchange with other countries. If more coin, or paper convertible into coin or bullion, circulated in Great Britain, compared with the business it had to perform than what circulated in other countries, its relative value would in consequence be diminished. Foreign bills would sell for a premium, the amount of which would be precisely equal to the excess of the value of the precious metals in the foreign market, caused by their redundancy in the home market; and, on the other hand, in the event of the currency becoming relatively deficient, its value would be proportionably increased;—bills drawn on foreign countries would sell at a discount, the amount of which would measure the excess of the relative value of the currency of this over that of other countries.

Manner of estimating the quantity of Bullion contained in the Coins of different Countries.

II. In estimating the comparative quantity of bullion contained in the currencies of different countries, a particular coin of one country, such as the British pound Sterling, is selected as an *integer* or standard of comparison, and the proportion between it and the coins of other countries of their *mint standard weight and fineness* is ascertained by experiment. A *par* of exchange is thus established; or rather it is ascertained, that a certain amount of the standard currency of any particular country contains precisely as much gold or silver of the same fineness, as is contained in the coin or integer with which it had been compared. This relation or *par*, as it is technically termed, is considered invariable; and allowance is made for the subsequent variations in the comparative quantity and purity of the bullion contained in the currencies of countries trading together, by rating the exchange at so much above or below *par*. In mercantile language, that country, by a comparison with one or other of whose coins the *par* of exchange has been established, is said to give the *certain* for the *uncertain*, and conversely. Thus, in the exchange between London and Paris, London and Hamburgh, &c., London gives the *certain*, or the pound Sterling, for an *uncertain* or variable number of francs, schillings, &c. Hence, the higher the exchange between any two countries, the more it is in favour of that which gives the *certain*, and the lower the more is it in favour of that which gives the *uncertain*.

Effects of variations in the value of metallic Currency on the Exchange.

On the supposition, which is very near the truth, that 25 francs contain the same quantity of standard bullion as a pound Sterling (25 francs, 20 centimes, is the exact par); and supposing also, that the relative value of bullion is the same in both countries, the exchange between London and Paris will be at *par*, when a bill drawn by a merchant in the one, on his correspondent in the other, sells at that rate; that is, when a bill of exchange for 2500 or 25,000 francs payable in Paris, sells in London for L.100 or L.1000, and *vice versa*. It is but seldom, however, that the coins of any country correspond exactly with the mint standard; unless, when newly issued, they are all either more or less worn; and whenever this is the case, an allowance corresponding to the difference between the actual value of the coins and their mint value, must be made in estimating "*the sum of the existing currency of either of two countries which contains precisely the same quantity of bullion as is contained in a given sum of the other.*" Thus, if the one pound Sterling was so worn, clipped, rubbed, &c. as not to contain so much bullion as 25 francs, but 10 *per cent.* less, the exchange between London and Paris would be at real *par*, when it was nominally 10 *per cent.* against London;* and if, on the other hand, the pound Sterling was equal to its mint standard, while the franc was 10 *per cent.* less, the exchange between London and Paris would be at real *par*, when it was nominally 10 *per cent.* against Paris, and in favour of London. If the currency of both countries was *equally* reduced below the standard of their respective mints, then it is obvious there would be no variation in the real *par*. But whenever the currency of countries trading together is depreciated in an *unequal* degree, the exchange will be nominally in favour of that country whose currency is least depreciated, and nominally against that whose currency is most depreciated.

---

* All restraints on the exportation of the precious metals were abolished in Great Britain in 1819. Their effect, for many years previous, could not be estimated at above ½ *per cent.*

It is almost unnecessary to refer to the history of the exchange to show the practical operation of this principle; and we shall content ourselves with selecting the following, from an infinite number of equally conclusive instances.

In a pamphlet printed in 1604, but written in 1564, it is mentioned, that when Henry VIII. degraded the several species of coin then current, there began to be "*some disorder*" in the price of all wares and commodities; which Edward VI., thinking to remedy by diminishing still farther the quantity of pure silver contained in each coin; the consequence was, that *the English pound Sterling, which heretofore exchanged abroad for 26 Flemish schillings, became worth no more than 13 Flemish schillings;* the price of English commodities being at the same time proportionably increased.—(Mr John Smith's *Memoirs of Wool*, Vol. I. p. 105. 8vo. ed.)

Previous to the great recoinage in the reign of William III., silver being at that time the metal in which payments were legally made, the *nominal* exchange between England and Holland, calculated according to the standard of their respective mints, was 25 *per cent.* against England; but, inasmuch as the real value of the English coin was, at that epoch, depreciated more than 25 *per cent.* below its mint value, the real exchange may notwithstanding have been in favour of England. The circumstance of the *nominal* exchange having become favourable to this country as soon as the new coin had been issued, renders this conjecture extremely probable.—(*Wealth of Nations*, Vol. II. p. 215.)

Before the reformation of our gold coin in 1774, the guinea contained so much less than its standard weight, that it was degraded 2 or 3 *per cent.* when compared with the French coin at the same period; and the exchange between England and France was then computed to be 2 or 3 *per cent. against* this country. Upon the reformation of the gold coin, the exchange rose to *par*. The Turkish government, in the course of the last forty years, has made three great alterations in the value of its coin. Before these frauds were committed, the Turkish *piastre* contained nearly as much silver as the English *half-crown;* and hence, in exchange, the *par* was estimated at *eight* piastres to the pound Sterling. The consequence of these repeated adulterations has been, the reduction of the silver in the piastre to one half, and a fall in the exchange of 100 *per cent.* bills on London having been bought in Turkey, in 1803, at the rate of 16 piastres for every pound Sterling.† Now, although it is not absolutely certain that these fluctuations in the *nominal* exchange were entirely owing to the alterations in the value of the coin, because the real exchange, or that which depends on the abundance or scarcity of bills in the market compared with the demand, might not be constant; yet the exact correspondence of the fall of exchange with the acknowledged degradation of the coin, renders it more than probable that it proceeded almost entirely from that degradation.‡

Effects of variations in the relative value of Gold and Silver on the Exchange.

When one country uses gold as the standard of its currency, and another silver, the *par* of exchange between these countries is affected by every variation in the relative value of these metals. When gold rises in value comparatively to silver, the exchange becomes nominally favourable to that country which has the gold standard, and *vice versa*. And hence, in making a correct estimate of the state of the exchange between those countries which use different standards, it is always necessary to advert to the comparative value of the metals which are assumed as such.

"For example," to use the words of Mr Mushet,

---

* It is necessary to observe, that it is here supposed that the clipped or degraded money exists in such a degree of abundance, as only to pass current at its bullion value. If the quantity of clipped money were *sufficiently limited*, it might, notwithstanding the diminution of weight, pass current at its mint value; and then the *par* would have to be estimated, not by its relative weight to foreign money, but by the mint price of bullion. This is a principle which must be constantly kept in view.

† Il est impossible d'indiquer exactement le *pair* des monnoies Turques. On voit des pieces du même nom, et frappées la même année, qui different de 100 *pour cent.* dans leur valeur intrinseque. (Storch, *Cours D'Economie Politique*, Tom. VI. p. 336.)

‡ *Observations on the Principles which regulate the Course of Exchange, by* William Blake, Esq. p. 41.

"If 34 schillings 11 grotes and ¼ of Hamburgh currency be equal in value to a pound Sterling, or 20/21 of a guinea, when silver is at 5s. 2d. *per* oz. they can no longer be so when silver falls to 5s. 1d. or 5s. an oz. or when it rises to 5s. 3d. or 5s. 4d.; because a pound Sterling in gold being then worth more or less silver, is also worth more or less Hamburgh currency.

"To find the real *par*, therefore, we must ascertain what was the relative value of gold and silver when the *par* was fixed at 34s. 11¼g. Hamburgh currency, and what is their relative value at the time we wish to calculate it.

"For example, if the price of standard gold was L.3, 17s. 10½d. *per* oz. and silver 5s. 2d., an ounce of gold would then be worth 15.07 ounces of silver, and twenty of our standard shillings would then contain as much pure silver as 34s. 11 grotes, and ¼. Hamburgh currency. But if the ounce of gold were L.3, 17s. 10½d. and silver 5s. (which it was on 2d January 1798), the ounce of gold would then be worth 15.57 ounces of silver. If L.1 Sterling at *par*, therefore, be worth 15.07 ounces of silver, then at 15.57 it would be at 3 *per cent.* premium; and 3 *per cent.* premium on 34s. 11¼. is 1 schilling 1 grote and 9/10, so that the *par* when gold is to silver as 15.57 to 1, will be 36 schillings 1 grote and 1/10. The above calculation will be more easily made by stating as "15.07 : 34-11¼ :: 15.57 : 36-1 1/10."*

In the Table of the Course of Exchange, &c. between London and Hamburgh from 1760 to 1819, annexed to this article, the fluctuations in the comparative value of gold and silver have been attended to throughout, and the true *par* calculated accordingly.

Effect of Seignorage on the Exchange.

As it is by their intrinsic worth as bullion that the relative value of the coins of particular countries is estimated in exchange, two coins of equal weight and purity are reckoned equivalent to each other, although the one should have been coined at the expence of the state, and the other charged with a *seignorage*, or duty on its coinage. Coins on which a *seignorage* is charged may, if not issued in excess, pass current in the country where they are coined, at a value so much higher than their value in bullion; but they will not pass at any higher value in other countries.†

Effect of variations in the value of paper currency on the Exchange.

But the principal source of fluctuations in the nominal price of bills of exchange is to be found in the varying value of the *paper* currency of commercial countries. The disorders which universally arose in rude ages from the diminution of the quantity of standard bullion contained in the coins of different countries, are now reproduced in another form, and often to a still more ruinous extent, in the depreciation of their paper currency.

The impossibility of retaining a comparatively large quantity either of coin or bullion, or of paper convertible into coin, in a particular country, previously to the Restriction Act of 1797, effectually limited the issues of the Bank of England, and sustained the value of British currency on a par with the currency of other countries. When the Bank issued less paper than was necessary for this purpose, the value of the currency being relatively great, it became profitable to import bullion, and to send it to the mint to be coined: And, on the other hand, when the Bank issued too much paper, and thereby depressed its value relatively to gold, it became profitable to demand payment of its notes in specie, and, thereafter, to export this specie either in the shape of coin or as bullion. In this way the Bank was compelled to limit its issues when excessive, and, consequently, to put a stop to the demand for gold, by rendering its paper of equal value.

Had the Bank of England, subsequently to the restriction, continued to issue only such quantities of paper as might have been required to sustain its value on a par with the value of gold, the act of 1797 would not have occasioned any real difference in our monetary system. But after the Bank had been released from all obligation to pay its notes, it was not to be expected that it should be very careful about limiting their number. The restriction *enabled* the Directors to exchange bits of engraved paper, worth perhaps not more than 5s. a quire, for as many, or the value of as many hundreds of thousands of pounds. And in such circumstances our only wonder is, not that paper money became depreciated, but that its value was not more degraded, —that a still greater quantity of bank-notes were not forced into circulation.

A country with an inconvertible paper currency, of which an undue proportion has been issued, is in a similar situation to what a country would be in if it were possessed of a relatively redundant gold and silver currency, and if the laws prohibiting the melting or exportation of the coin could be carried into full effect. Such a currency is necessarily confined to the country where it is issued; it cannot, when too abundant, diffuse itself generally amongst others. The level of circulation is destroyed; and the value of the currency becoming less than the value of the currency of other countries, the nominal exchange is rendered proportionably unfavourable.

Supposing that nothing but silver coin of the standard weight and purity (25 francs of which would exchange for a pound Sterling of the British mint standard) circulates at Paris, and that the circulating medium of London is composed entirely of paper only worth half its nominal value, or which is depreciated 100 *per cent.*,—in that case the exchange between London and Paris would be at *real* par, when it was nominally *cent. per cent.* against London and in favour of Paris. Double the amount of this depreciated London currency would be required to purchase a bill of exchange on Paris where the currency retained its value, while half the former amount of Parisian currency would now suffice to purchase a bill payable in London. The effects of such a depreciation would be precisely the same with those which would follow from a similar reduction in the value of metallic money. While paper money, depreciated 100 *per cent.*, constituted our legal currency, a pound note, instead of being worth 25 francs, would only be worth 12½; and the nominal or numerical value of the bills of exchange negociated between this country and France would be regulated accordingly:—that is, a bill of exchange for L.100 or L.1000 payable in London, would sell in Paris for 1250 or 12,500 francs, and conversely. If, while the currency of London remained steady at 100 *per cent.* below its mint value, Parisian currency should, either from the coins becoming deficient in weight, or because of an inordinate issue of paper money, become also depreciated, the *nominal* exchange would be rendered proportionably less unfavourable to London. On the hypothesis that the currency of Paris is depreciated 50 and that of London 100 *per cent.* the *nominal* exchange would be 50 *per cent.* against the latter, and so on. Thus it appears, that the *nominal* exchange between any two or more places will always be adjusted in proportion to the relative value of their currencies: being most favourable to that country whose currency approaches nearest to its mint standard, and most unfavourable to that whose currency is most degraded.

---

* *An Inquiry into the Effects produced on the National Currency by the Bank Restriction Bill, &c. by* Robert Mushet, Esq. second edit. p. 94.

† Previous to 1817, no seignorage had for a very long period been deducted from either the gold or silver coins of Great Britain; but in the great recoinage of that year, the value of silver was raised from 5s. 2d. to 5s. 6d. an ounce, or nearly in the proportion of 6½ *per cent.* The gold coins, however, are still coined free of expence, and no variation has been made in their standard. The British mint proportion of silver to gold is now as 14 287/1000 to 1; that is, one ounce of standard gold bullion is rendered exchangeable for 14 287/1000 ounces of standard silver. In France, the mint proportion of the two metals is as 15½ to 1; a seignorage being exacted of nearly ⅓ *per cent.* on gold, and 1½ *per cent.* on silver.

Exchange between Great Britain and Ireland subsequent to 1797.

The state of the exchange between Great Britain and Ireland subsequently to the restriction on cash payments in 1797, furnishes a striking proof of the effects which inordinate issues of paper have in depressing the exchange.

The nominal value of the Irish shilling having been raised from 12d. to 13d., or, which is the same thing, L.108, 6s. 8d. of Irish money having been rendered only equal to L.100 of British money, it follows, that when the exchange between Great Britain and Ireland is at 8⅓ *per cent.* against the latter, it is said to be at *par*. In the *eight* years previous to 1797, when the paper currency both of England and Ireland was convertible into gold, the exchange between London and Dublin fluctuated from 7½ to 9 *per cent.*, that is, from ⅚ *per cent.* in favour of Dublin, to ⅔ *per cent.* against it. In September 1797, it was so low as 6 *per cent.*, or 2⅓ *per cent.* in favour of Dublin. The amount of the notes of the Bank of Ireland in circulation in January 1797 was only L.621,917; but in April 1801, they had increased to L.2,286,471, and the exchange was then at 14 *per cent.*, or 5⅔ *per cent. against* Dublin. In 1803, the Bank of Ireland notes in circulation averaged L.2,707,956, and in October of that year the exchange rose to 17 *per cent.*, that is, to 8⅔ *per cent.* against Dublin!

The fact of the exchange between London and Dublin having fluctuated so very little from real par for eight years previous to the restriction, shows that the circulating medium of Great Britain and Ireland had then been adjusted very nearly according to the relative wants of the two countries. But, in these circumstances, it was evidently impossible, supposing the value of British currency to have remained stationary, that the quantity of Irish bank paper could be nearly *quintupled* in the short space of six years, without rendering the currency of Ireland comparatively redundant, and sinking its value below that of England. Had the Bank of England increased its notes nearly in the same ratio as the Bank of Ireland, then, as the currency of both countries would have been *equally depreciated*, the exchange between London and Dublin would have continued at *par*. But while the notes of the Bank of Ireland were increased from L.621,917 to L.2,707,956, or in the proportion of 1 to 4.3, those of the Bank of England were only increased from L.9,181,843 (their number on 7th January 1797), to L.16,505,272, or in the proportion of 1 to 1.8. If the Bank of England had not made this addition to its issues, the exchange would obviously have been still more unfavourable to Dublin.

In the debates on the Bullion Report, it was contended that the increase of Bank of Ireland paper could not be the cause of the exchange becoming unfavourable to Dublin, inasmuch as it had again become favourable, after the issues of the Bank of Ireland had been still further increased. Nothing, however, can be more inconclusive than such reasoning. Before it can be brought to have the least incidence on the case in question, it must be shown that the value of the currency of Great Britain had, in the interim, remained stationary, or that it had not been depreciated to the same extent as that of Ireland. Unless this can be established, the circumstance of the exchange between London and Dublin coming to par, while as many notes of the Bank of Ireland circulated as in the period of its greatest depression, will not authorise us to conclude that the increase of Irish Bank paper previously to 1804 had not been the cause of the then fall in the exchange. For, it is obvious that the depreciation of Irish Bank paper might be going on subsequently to 1804; and yet, on the supposition that the depreciation of English Bank paper had gone on still more rapidly, the exchange must necessarily have become more favourable to Dublin. This is just supposing the circumstances which took place in the first six years of the restriction, to be reversed in the second six. Let us examine how the fact stands.

We have just seen that, in 1803, when the exchange was nominally 10 *per cent.* against Dublin, the issues of the Bank of England amounted to L.16,505,272, and those of the Bank of Ireland to L.2,707,956. And, by referring to the account of the issues of the Bank of Ireland from 1797 to 1819, annexed to this article, it will be seen that, in 1805, 1806, 1807, and 1808, they were rather *diminished;* and that, in 1810, they only amounted to L.3,251,750, being an increase of not more than L.543,794, in the space of seven years, or at the rate of $2\frac{6}{7}$ *per* *cent. per annum;* but, in the same period (from 1803 to 1810), the issues of the Bank of England had increased from L.16,505,272 to L.22,541,596, or at the rate of 5 *per cent. per annum.* But this is not all: According to Mr Wakefield (*Account of Ireland,* Vol. II. 171), who has left no subject untouched which could throw light on the state of Ireland, there were *fifty* registered bankers in that country in 1804, and only *thirty-three* in 1810, of which fourteen were new houses, thirty-one of the old establishments having disappeared; "and I believe," says Mr Wakefield, "*for the most part failed.*" This extraordinary diminution of the country paper of Ireland, for the reduction of the issues was at least proportionate to the reduction in the number of banks, must have greatly raised its value, and would have counteracted a very great increase in the issues of the National Bank. Now the very reverse of all this took place in Britain. In 1800, there were 386 country banks in this country; and, in 1810, this number, instead of being diminished, as in Ireland, had increased to 721, having at least twice the number of notes in circulation in the latter as in the former period!

It appears, therefore, that when, in the period between 1797 and 1804, the quantity of paper in circulation in Ireland was increased, and consequently its value depressed, faster than in England, the exchange between London and Dublin became proportionably unfavourable to the latter; and, on the other hand, it appears that when, in the six years subsequent to 1804, the paper currency of England was increased more rapidly than the paper currency of Ireland, its relative value was diminished, and the *nominal* exchange became more favourable to Dublin.

But, however conclusive this must appear, there is still stronger and more decisive evidence to show that the unfavourable exchange of Dublin upon London in 1802, 1803, 1804, &c. was entirely owing to the comparative redundancy, or depreciation, of Irish Bank paper. The linen manufacturers, weavers, &c. and the majority of the other inhabitants of a few counties in the north of Ireland, being, at the period of the restriction, strongly disaffected towards government, they almost unanimously refused to receive bank notes, either in payment of commodities or as wages. The landlords, having also stipulated for the payment of their rents in specie, the consequence was, that a gold currency was maintained in the north of Ireland long after it had been entirely banished from the southern part of the island. If, therefore, the depressed state of the exchange between London and Dublin had been occasioned, as was contended by the advocates of the restriction, either by an unfavourable balance of trade between Ireland and Great Britain, or by remittances from the former on account of absentee landlords, &c. it would have been equally depressed between London and the commercial towns in the northern counties. But, so far from this being the case, in December 1803, when the exchange of Dublin on London was at 16¼ *per cent.*, that of Belfast on London was at 5¼. Or, in other words, at the same time that the exchange between Dublin and London was about 8 *per cent. against* Ireland, the exchange between Belfast, *which had a gold currency,* and London, was about 3 *per cent.* in its *favour.* Nor is this all. There was not only a difference of 11 *per cent.* in the rate of exchange between Dublin and London, and Belfast and London, but the *inland* exchange between Dublin and Belfast was, at the same time, about 10 *per cent.* in favour of the latter; that is, bills drawn in Dublin, and payable in the gold currency of Belfast, brought a premium of 10 *per cent.*, while bills drawn in Belfast, and made payable in the paper currency of Dublin, sold at 10 *per cent.* discount.*

It is unnecessary, we conceive, to refer particularly to the history of the French *assignats,* or of the paper currency of the other continental powers, and of the United States, to corroborate what has been here advanced. Such of our readers as wish for more detailed information, may have recourse to the sixth volume of the *Cours D'Economic Politique,* of M. Storch, where they will find a very able, perspicuous, and instructive account of the effects produced by the issues of paper on the price of bullion and the exchange in almost every country in Europe. They are, in every case, precisely similar to those we have just stated.

It now only remains to determine the effects of fluctuations in the *nominal* exchange on the export and import trade of the country.

Inquiry into the effects of fluctuations in the nominal Exchange on Export and Import Trade.

When the exchange is at *par,* the operations of the merchant are regulated entirely by the difference between foreign prices and home prices. He imports those commodities which can be sold at home for so much more than their price abroad, as will, after indemnifying him for the expence of freight, insurance, &c. yield an adequate remuneration for his trouble, and for the capital employed in importing them; and he exports those whose price abroad is so much greater than at home as will suffice to cover all expences, and to afford a similar profit. But when, because of a fall in the value of its currency, the *nominal* exchange becomes unfavourable to a particular country, the premium which its merchants receive on the sale of foreign bills, has been supposed capable of enabling them to export with profit in cases where the difference between the price of the exported commodities at home and abroad might not be such as would have permitted their exportation had the exchange been at *par.* Thus, if the *nominal* exchange was 20 *per cent.* against this country, a merchant who had consigned goods to his agent abroad, would receive a premium of 20 *per cent.* on the sale of the bill; and if we suppose freight, insurance, mercantile profit, &c. to amount to 12 or 15 *per cent.* it would at first sight appear as if our merchants might, in such circumstances, export commodities, although their price at home should be 5 or 8 *per cent.* higher than in other countries. If, on the other hand, the *nominal* exchange was in our favour, or if bills *on* this country sold at a premium, it would appear as if foreigners would then be enabled to consign goods to our merchants, or our merchants to order goods from abroad, when the difference of real prices was not such as would of itself have led to an importation.'

---

* Farther information on this interesting subject may be obtained from the very able *Report of the Committee of the House of Commons,* appointed in 1804 to inquire into the state of the circulating paper in Ireland, its specie, &c. and the state of the exchange between it and Great Britain; in Mr. Parnell's excellent pamphlet on the same subject; and in the pamphlets of Lord King, Mr Huskisson, &c.

But a very little consideration will convince us that fluctuations in the *nominal* exchange can have no such effect. The same fall in the value of the currency which renders the exchange unfavourable, and causes foreign bills to sell at a premium, must *equally increase* the price of all commodities. And hence, whatever might be the amount of the premium which the exporter gained by the sale of the bill drawn on his correspondent abroad, it would do no more than indemnify him for the enhanced price of the goods exported. Mercantile operations are, in such cases, conducted precisely as they would be if the exchange was really at *par;* that is, by a comparison of the real prices of commodities at home and abroad, meaning, by real prices, the prices at which they would be sold, provided there was no depreciation of the currency. If those prices are such as to admit of exportation or importation with a profit, the circumstance of the nominal exchange being favourable or unfavourable, will make no difference whatever on the transaction.

" Suppose," says Mr Blake, who has very successfully illustrated this part of the doctrine of exchange, " the currencies of Hamburgh and London being in their due proportions, and therefore the *nominal* exchange at *par*, that sugar, which, from its abundance in London, sold at L.50 *per* hogshead, from its scarcity at Hamburgh, would sell at L.100. The merchant in this case would immediately export. Upon the sale of his sugar, he would draw a bill upon his correspondent abroad for L.100, which he could at once convert into cash, by selling it in the bill market at home, deriving from this transaction a profit of L.50, under deduction of the expences of freight, insurance, commission, &c. Now, suppose no alteration in the scarcity or abundance of sugar in London and Hamburgh, and that the same transaction were to take place, after the currency in England had been so much increased, that the prices were doubled, and, consequently, the *nominal* exchange 100 *per cent.* in favour of Hamburgh, the hogshead of sugar would then cost L.100, leaving apparently no profit whatever to the exporter. He would, however, as before, draw his bill on his correspondent for L.100; and, as foreign bills would bear a premium of 100 *per cent.*, he would sell this bill in the English market for L.200, and thus derive a profit from the transaction of L.100 depreciated pounds, or L.50 estimated in undepreciated currency, deducting, as in the former instance, the expence of freight, insurance, commission, &c.

" The case would be precisely similar, *mutatis mutandis*, with the importing merchant. The unfavourable *nominal* exchange would appear to occasion a loss, amounting to the premium on the foreign bill, which he must give in order to pay his correspondent abroad. But if the difference of *real* prices in the home and foreign markets were such, as to admit of a profit upon the importation of produce, the merchant would continue to import, notwithstanding the premium; for that would be repaid to him in the advanced *nominal* price at which the imported produce would be sold in the home market.

" Suppose, for instance, the currencies of Hamburgh and London being in their due proportions, and, therefore, the *nominal* exchange at *par*, that linen, which can be bought at Hamburgh for L.50, will sell here at L.100. The importer immediately orders his correspondent abroad to send the linen, for the payment of which he purchases at L.50 a foreign bill in the English market, and on the sale of the consignment for L.100 he will derive a profit, amounting to the difference between L.50 and the expence attending the import.

" Now, suppose the same transaction to take place, without any alteration in the scarcity or abundance of linen at Hamburgh and London, but that the currency of England has been so augmented, as to be depreciated to half its value, the *nominal* exchange will then be 100 *per cent.* against England, and the importer will not be able to purchase a L.50 foreign bill for less than L.100. But as the prices of commodities here will have risen in the same proportion as the money has been depreciated, he will sell his linen to the English consumer for L.200, and will, as before, derive a profit amounting to the difference between L.100 depreciated, or L.50 estimated in undepreciated money, and the expences attending the import.

" The same instances might be put in the case of a favourable exchange; and it would be seen in the same manner, that *nominal* prices and the *nominal* exchange being alike dependent on the depreciation of currency, whatever apparent advantage might be derived from the former, would be counterbalanced by a loss on the latter, and *vice versa*."—(*Observations, &c.* p. 48.)

It appears, therefore, that fluctuations in the *nominal* exchange have no effect on export or import trade. A fall in the exchange obliges the country to which it is unfavavourable, to expend a larger *nominal* sum in discharging a foreign debt than would otherwise be necessary; but it does not oblige it to expend a greater *real* value. The depression of the *nominal* exchange can neither exceed nor fall short of the comparative depreciation of the currency. If the depreciation of British currency amounted to 100 or 1000 *per cent.* the *nominal* exchange would be 100 or 1000 *per cent.* against us; and we should be compelled in all our transactions with foreigners to give them L.2, or L.10, for what might otherwise have been procured for L.1. But as neither L.2, nor L.10, of paper, depreciated to the extent of 100 or 1000 *per cent.*, would be more valuable than one pound of undepreciated paper, payment of a foreign debt might, it is evident, be just as easily made in the one currency as in the other; and mercantile transactions would, in such circumstances, be conducted exactly as they would have been had the currency been undepreciated, and the *nominal* exchange at *par*.

It is necessary, however, before dismissing this part of our subject, particularly to examine the effects of fluctuations in the *nominal* exchange on the importation and exportation of *bullion*. In certain cases they form an exception to the general principle we have been endeavouring to elucidate.

Effects of fluctuations in the Nominal Exchange on the trade in Bullion.

If the *nominal* exchange were to become unfavourable to a country which had entirely discarded the precious metals from its circulation, Mr Blake's opinion that the fall of the exchange has no effect on the export and import of bullion, more than of any other commodity, would be perfectly well founded. In this case the price of all sorts of commodities, and of bullion among the rest, would be increased precisely according to the depreciation of the currency; and the merchants who should, in such circumstances, attempt to export bullion, would find that its increased price in the home market would be exactly equivalent to whatever premium they might gain by the sale of the bills drawn on their agents abroad for its price. But when the *nominal* exchange becomes unfavourable to a country whose currency either consists entirely of the precious metals, or partly of them and partly of paper, a different effect would be produced.

In this case the depreciation would necessarily add to the stock of bullion in the country. For, as soon as the currency had been depreciated to such an extent, as to render the excess of the market above the mint price of bullion sufficient to cover the very trifling expences attending the melting of the coin, and to afford some little remuneration for the trouble of the melters, they would immediately set about converting it into bullion. If, indeed, it were possible to realize a greater profit by the exportation than by the fusion of the coins, they would not be converted into bullion, and, of course, its real price would continue stationary. But this is very seldom the case. The operation of melting is so extremely simple, and requires so very little apparatus, that it may, in almost every instance, be carried on at a much less expence than would be necessary to export the coins. The cost attending the conveyance of gold to France varies, in a season of peace, from 1 to 2 *per cent.*; while a profit of ¼ or ½ *per cent.* is sufficient to indemnify the melters of guineas or sovereigns. It is obvious, therefore, that of the two modes of restoring the value of the currency when it becomes depreciated, or relatively redundant, that of fusion will be generally resorted to in preference to exportation. Should the redundancy of the currency be inconsiderable, all the addition which the operations of the melters could make to the supply of bullion, would most probably be insufficient to occasion any perceptible fall in its *real* price. But, in every case in which the redundancy or depreciation of the currency is considerable, the fusion of the coined money never fails to increase the quantity of bullion beyond the effectual demand, and, consequently, to occasion a fall in its *real* price, and to render it a profitable article of export. The demand for bullion, though it must always vary with the varying wealth and riches of the community, fluctuates very little in periods of limited duration; and no considerable addition can ever be made to the stock on hand in a particular country, without sinking its value and causing its egress.

Mr Blake contends, that this exportation of bullion is the effect of the melting of the coin, and not the cause of it; and in so far he is certainly right. But we do not see how this in the least strengthens his opinion, that fluctuations in the *nominal* exchange, even in those cases in which the currency consists either wholly or partially of the precious metals, have no influence on the export and import of bullion. Surely it is impossible to deny, that the fusion of the coin, of which Mr Blake admits the exportation of bullion is a necessary consequence, is occasioned by a redundancy of the currency, or by the same cause which occasions an unfavourable *nominal* exchange.

Bullion, therefore, forms an exception, and it is the only one, to the general principle that a fall in the value of the currency, or an unfavourable *nominal* exchange, has no effect on importation or exportation. But this exception does not take place, except in those cases in which the currency consists either in *whole* or in *part* of the precious metals. When the currency consists *entirely* of paper, or of any commodity other than gold or silver, its depreciation can have no influence whatever on the importation of bullion.

SECTION II.—*Real Exchange.*

Real Exchange.

Having thus endeavoured to trace the effects which variations in the value of the currencies of countries maintaining an intercourse together have on the exchange; we shall now proceed to consider how far it is influenced *by fluctuations in the supply and demand for bills*. To facilitate this inquiry, we shall exclude all consideration of changes in the value of money; or, which is the same thing, we shall suppose the currencies of the different countries having an intercourse together to be all fixed at their mint standards, and that each has its proper supply of bullion.

When two nations trade together, and each purchases from the other commodities of precisely the same value, their debts and credits will be equal, and, of course, the real exchange will be at *par*. The *bills* drawn by the one will be exactly equivalent to those drawn by the other, and their respective claims will be adjusted without requiring the transfer of bullion, or other valuable produce. But it very rarely happens that the debts reciprocally due by any two countries are equal. There is almost always a balance owing on one side or other; and this balance must affect the exchange. If the debts due by London to Paris exceeded those due by Paris to London, the competition in the London market for bills on Paris would, because of the comparatively large sum which our merchants had to remit to France, be greater than the competition in Paris for bills on London; and, consequently, the *real* exchange would be in favour of Paris and against London.

Limit to fluctuations in the Real Exchange.

The expence of the transfer of bullion from one country to another, constitutes the limit within which the rise and fall of the *real* exchange between them must be confined. In this respect, as in most others, transactions between foreign countries are regulated by the very same principles which regulate those between different parts of the same country. We have already shown how the fluctuations, in the *real* exchange between London and Glasgow, could never exceed the expence of transmitting money between those cities. The same principle holds universally. Whatever may be the expence of transmitting bullion, or the money of the commercial world, between London and Paris, Hamburgh, New York, &c., it is impossible that the *real* exchange of the one on the other should, for any considerable period, be depressed to a greater extent. For no merchant will ever pay a greater premium for a bill to discharge a debt abroad, than what would suffice to cover the expence of transmitting bullion to his creditor.

Hence it appears, that whatever has a tendency to obstruct or fetter the intercourse between different countries, must also have a tendency to widen the limits within which fluctuations in the *real* exchange may extend. It is this principle which enables us to account for its varying so much more in time of war than in time of peace. The amount of the bills drawn on a country engaged in hostilities is, from various causes which we shall afterwards notice, liable to be suddenly increased; though it is certain, that whatever may be the amount of the bills thus thrown into the market, the depression of the exchange cannot, for any length of time, exceed the expence of conveying bullion from the debtor to the creditor country. But during war this expence is increased; the charges on account of freight, insurance, &c., being then necessarily augmented. It appears from the evidence annexed to the *Report of the Bullion Committee*, that the expence of conveying gold from London to Hamburgh, which, previously to the war, only amounted to 2 or 2½ *per cent.*, had, in the latter part of 1809, increased to about 7 *per cent.*; showing, that the limits within which fluctuations in the real exchange were confined in 1809, were about *three* times as great as those within which they were confined in 1793.

This principle also enables us to account for the greater steadiness of the real exchange between countries in the immediate vicinity of each other. The expence of transmitting a given quantity of bullion from London to Dublin or Paris, is much less than the expence of transmitting the same quantity from London to New York or Petersburgh. And, as fluctuations in the *real* exchange can only be limited by the cost of transmitting bullion, they may consequently extend much farther between distant places, than between those that are contiguous.

Inquiry into the circumstances which give rise to a favourable or an unfavourable balance of payments.

It will now be proper to investigate the circumstances which gave rise to a favourable or an unfavourable balance of payments, and to appreciate their effects on the real exchange, and on the trade of the country in general. As this is one of the most important inquiries in the whole science of political economy, it will require to be discussed at some length.

A very great, if not the principal source of the errors into which practical merchants and the majority of writers on the subject of exchange have been betrayed, appears to have originated in their confounding together the sum which imported commodities are worth in the home market, with the sum which they cost in the foreign market. It is obviously, however, by the amount of the latter only, that the balance of payments, and consequently the *real* exchange, is influenced. A cargo of iron, for example, which had been bought in Gottenburgh for L.1000, might be worth L.1400 or L.1500 when imported into England; but the foreign merchant would not be entitled to draw a bill on London for more than its original cost or L.1000. It is clear, therefore, even on the slightest consideration, that the circumstance of the value of the imports exceeding the value of the exports, does not authorise the conclusion that the balance of payments is unfavourable. A favourable or an unfavourable balance depends entirely on the fact whether the sum due *to* foreigners for commodities imported from abroad, is less or more than the sum due *by* them for the commodities they have purchased; but it has nothing to do with the prices which may eventually be obtained for the imported or exported commodities.

The fact of the value of the Imports exceeding the value of the Exports does not warrant the conclusion that the balance of payments is unfavourable.

The great object of the *mercantile* system of commercial policy, a system which still continues to preserve the ascendancy in this and in every other country in Europe, is, to create a favourable balance of payments, and, consequently, a favourable *real* exchange, by facilitating exportation and restricting importation. It is foreign to the object of this article to enter into any examination of the principles of this system, except in so far as they are connected with the subject of exchange; but we hope to be able to show, in opposition to the commonly received opinions on the subject, that in every country carrying on an advantageous commerce, the value of the imports must always exceed the value of the exports; and that this excess of importation has not, in ordinary cases, the least tendency to render the *real* exchange unfavourable.

In countries carrying on an advantageous commerce, the value of the Imports must always exceed the value of the Exports.

The proper business of the merchant consists in carrying the various products of the different countries of the world from those places where their exchangeable value is least to those where it is greatest; or, which is the same thing, in distributing them according to the effective demand. It is clear, however, that there could be no motive to export any commodity unless the commodity which it was designed to import in its stead was of greater value. When an English merchant commissions 100,000 quarters of Polish wheat, he calculates on its selling for so much more than its price in Poland, as will be sufficient to pay the expence of freight, insurance, &c.; and to yield, besides, the common and ordinary rate of profit on the capital employed in making the transfer. If the wheat did not sell for this sum, its importation would obviously occasion a loss to the importer. No merchant ever did or ever will export but with the view of importing a greater value in return. And so far from an excess of exports over imports being any criterion of an advantageous commerce, it is quite the reverse; and the truth is, notwithstanding all that has been said and written to the contrary, that unless the value of the imports exceeded the value of the exports, foreign trade could not be carried on. Were this not the case—were the value of the exports always greater than the value of the imports, merchants would lose on every transaction with foreigners, and the trade with them would either have no existence at all, or if begun, would have to be speedily relinquished.

In England, the rates at which exports and imports are valued, were fixed so far back as 1696. But the very great alteration that has since taken place, not only in the value of money, but also in the real price of most part of the commodities produced in this and other countries, has rendered this *official* valuation of no use whatever as a criterion of the true value of the exports and imports. In order to remedy this defect, an account of the real, or *declared* value of the exports is annually prepared and laid before Parliament; but even this is very far from accurate. It must always be the interest of the merchant to endeavour to conceal the real amount of the goods imported on which duties are charged; while, on the other hand, it is very frequently his interest to magnify the amount of those commodities on the export of which either a bounty or a drawback is allowed.

If perfectly accurate accounts could be obtained of the value of the exports and imports of a commercial country, there can be no manner of doubt that in ordinary years there would be always an excess of imports over exports. The value of an exported commodity is estimated at the moment of its being sent abroad, and *before* its value is increased by the expence incurred in transporting it to the place of its destination; but the value of the commodity imported in its stead is estimated *after* it has arrived at its destination, and, consequently, after its value has been enhanced by the cost of freight, insurance, importer's profit, &c.

It is of very little importance, in as far at least as the interests of commerce are concerned, whether a nation acts as the carrier of its own imports and exports, or employs others. A carrying nation will appear to derive a comparatively large profit from its commercial transactions; but this excess of profit is nothing more than a fair remuneration for the capital employed and the risk incurred in transporting commodities from one country to another. If the whole trade between this country and France was carried on in British bottoms, our merchants, in addition to the value of the goods exported, would also receive the expence of the carriage to France. This, however, would not occasion any loss to that country. The French merchants must pay the freight of the commodities they import; and if the English can afford it on cheaper terms than their own countrymen, there can be no good reason why they should not employ them in preference.

In the United States the value of the imports, as ascertained by the Customhouse returns, always exceeds the value of the exports. And although our practical politicians consider the excess of exports over imports as the only sure criterion of an advantageous commerce, "it is nevertheless true, that the real gain of the United States has been nearly in proportion as their imports have exceeded their exports."* This has in part been occasioned by the Americans generally exporting their own surplus produce, and consequently receiving from foreigners, not only an equivalent for their exports, but also for the cost of conveying them to the foreign market. In 1811, says the author just quoted, flour sold in America for nine dollars, 50 cents *per* barrel, and in Spain for 15 dollars. The value of the cargo of a vessel carrying 5000 barrels of flour would, therefore, be estimated at the period of its exportation at 47,500 dollars; but as this flour would, because of freight, insurance, exporter's profits, &c., sell in Spain for 75,000 dollars, the American merchant would be entitled to draw on his agent in Spain for 27,500 dollars more than the flour cost in America, or than the sum for which he could have drawn had the flour been exported on account of a Spanish merchant. If, as is most probable, the 75,000 dollars were invested in some species of Spanish or other European goods, the freight, insurance, &c., on account of the return cargo, would perhaps increase its value to 100,000 dollars, so that in all the American merchant might have imported commodities worth 52,500 dollars more than the flour originally sent to Spain. It is as impossible to deny that such a transaction as this is advantageous, as it is to deny that its advantage consists entirely in the excess of the value of the goods imported over those exported. And it is equally clear, that, although such transactions as the above had been multiplied to an inconceivable extent, America might notwithstanding have had the real balance of payments in her favour.

Instead, therefore, of endeavouring to fetter and restrict the trade with those countries from which we should otherwise import a greater value than we exported, we ought, on the contrary, to give it every possible facility. There is not a private merchant in the kingdom who does not consider that market as the best in which he is enabled to obtain the highest price, or the greatest value in exchange for his goods; why then should he be excluded from it? Why compel him to dispose of a cargo of muslin for L.10,000 rather than L.12,000? The wealth of a state is made up of the wealth of individuals; and it is impossible that any more effectual method of increasing individual wealth can be devised than to permit every person to make his purchases in the cheapest and his sales in the dearest market.

Erroneous notions relative to the balance of trade, have been the cause of the restrictions which have annihilated the trade with France.

It would be difficult to estimate the mischief which absurd notions relative to the balance of trade have occasioned in almost every commercial country. In Great Britain, they have been particularly injurious. It is owing entirely to the prevalence of prejudices to which they have given rise, that the restrictions imposed on the trade between this country and France are to be ascribed. The great, and, indeed, the only argument insisted on by those who prevailed on the Legislature to declare the trade with France a *nuisance (Prohibition Act, 1st William and Mary)*, was founded on the fact, that the value of the imports from that kingdom considerably exceeded the value of the commodities we had exported! This balance was termed a *tribute* paid by England to France; and it was sagaciously asked, what had we done that we should be obliged to pay so much money to our deadly enemy? It never occurred to these wise persons, that no merchant would import a single ounce of any commodity from France, unless it would bring a higher price in this country than the commodity with which it had been bought; and that the profit of the merchant, or, which is the same thing, the national gain, would be in exact proportion to this excess of price. The very reason assigned for prohibiting the trade affords the best possible proof of its having been a lucrative one. Nor can there be any doubt that an unrestricted freedom of intercourse between the two countries would still be of the greatest service to both. The peculiarities in the soil and climate, as well as in the national character of the people of Great Britain and France, will always enable the one to produce various species of raw and manufactured commodities at a cheaper rate than they could possibly be produced by the other. If we were allowed freely to purchase the silks, the wines, and the brandies of France, those commodities which we can produce at a cheaper rate than our ingenious neighbours would be taken in payment. An extensive market would thus be created for many species of our commodities, and a natural and powerful stimulus would be applied to the industry of both countries. Nobody will be hardy enough to deny that the trade with America, Portugal, and the Baltic is advantageous; and, if so, what possible reason can be given why the trade with France should be considered as prejudicial? Surely no person can be silly enough to suppose that our merchants would export or import any commodity to or from France, which they could either sell or buy on better terms any where else. If the restrictions on the French trade are not really injurious, that is, if the trade be either a losing or a less advantageous one than the trade with other countries, we may rest assured that the throwing it open would not induce a single merchant to engage in it.

---

* Pitkin on the *Commerce of the United States*, 2d Ed. p. 280.

As the real price of every species of commodities must always be proportionable not only to the expence of their production, but also to the expence necessarily incurred in conveying them from where they have been produced to where they are to be consumed, it is certain that a nation which prohibits trading with the countries in her immediate vicinity must pay a higher price for her imported commodities, and be obliged to exact a higher price for those which she exports, than would have been necessary had she been able to procure the one, or to dispose of the other, in her immediate neighbourhood. If wine of the same intrinsic worth could be bought at Bourdeaux equally cheap as at Lisbon, the difference of freight would enable it to be sold cheaper in London. It is this principle, in fact, which renders the home trade so peculiarly advantageous. The parties who make the exchange live near each other, and, consequently, each obtains the commodity of which he stands in need at its cheapest rate, and without being obliged to pay any great additional sum on account of carriage. When, therefore, we restrict the trade with countries in our immediate vicinity, we act in the teeth of that very principle which is, in every other case, admitted to be advantageous. We compel the purchasers of foreign commodities to pay a higher price for them than would otherwise have been necessary; while, by raising the price of our own exported commodities, the market for them is unnaturally and injuriously contracted.[*]

But the partisans of the exclusive or mercantile system will perhaps tell us, that they do not mean to contend, that it is profitable to export a greater actual value than is imported, but that, by exporting an excess of raw and manufactured commodities, the balance of payments is rendered favourable, and that this balance (which they consider as equivalent to the entire nett profit made by the country in its transactions with foreigners) is always paid in *bullion*.

Favourable or unfavourable balance not always received or paid in Bullion.

It will, however, be an extremely easy task to show that this statement is altogether erroneous; that an unfavourable balance is seldom or never discharged by means of bullion; and that this balance is not a measure, and has, in fact, nothing to do with the profit or loss attending foreign commercial transactions.

1. As long as the premium on foreign bills is less than the expence attending the transit of bullion from a country which has an unfavourable real exchange, it is certain that no merchant will ever think of subjecting himself to an unnecessary expence, by exporting bullion to pay a foreign debt. But supposing the premium on foreign bills to have increased, so as to equal the cost of exporting the precious metals, for it cannot *exceed* this sum, it does not by any means follow that they will therefore be exported. That depends entirely on the fact, whether bullion is, at the time, the cheapest exportable commodity, or, in other words, whether a remittance of bullion is the most advantageous way in which it is possible to discharge a debt. If a London merchant owes a debt of L.100 in Paris, it is his interest to find out the cheapest method of paying it. On the supposition, that the *real* exchange is 2 *per cent.* below *par*, and that the expence of remitting bullion, including the profit of the bullion merchant, is also 2 *per cent.*, it will be indifferent to the London merchant, whether he pays L.2 of premium for a bill of L.100 payable in Paris, or incur an expence of L.2, by remitting L.100 worth of bullion directly to that city. If the relative prices of cloth in Paris and London are such, as would require L.103 to purchase and pay the expence of sending as much cloth to Paris as would sell for L.100, he would undoubtedly prefer buying a bill, or exporting bullion. But if, by incurring an expence of L.101, the debtor is enabled to send as much hardware to Paris as would sell for L.100, he would as certainly prefer paying his debt by an exportation of hardware. By doing so, he would save 1 *per cent.* more than if he had bought a foreign bill, or remitted bullion, and 2 *per cent.* more than if he had exported cloth. If there had been any other commodity whose exportation would have been

more advantageous, he would have used it in preference.

It is obvious, therefore, that the exportation of bullion is regulated by precisely the same principles which regulate the export and import of other commodities. It is exported when its exportation is most advantageous; that is, when it is less valuable at home, and more valuable abroad, than any other commodity; and it cannot possibly be otherwise exported. The balance of payments might be a thousand millions against a particular country, without causing the exportation of a single ounce of bullion. No merchant would remit L.100 worth of gold or silver from England to discharge a debt in Paris, if he could invest L.99, L.98, or any smaller sum in any other species of merchandise which, exclusive of expences, would sell in France for L.100. The merchant who deals in the precious metal is, we may depend upon it, as much under the influence of self-interest, as the merchant who deals in coffee or indigo. But what merchant would attempt to discharge a foreign debt, by exporting coffee which cost L.100, when he might effect the same object by sending abroad indigo which cost only L.95? No person in his senses would export a hat to be hold for 20s., provided he could sell it at home for a *guinea;* nor would any person export an ounce of bullion, if its value was not less in the exporting than in the importing country, or if there was any other commodity, whatever that might be, exported with greater advantage.

2. It is in vain to contend, that, by permitting an unrestricted freedom of trade, a particular state might become indebted to another, which had no demand for any species of ordinary merchandise, and which would only accept of cash or bullion in exchange for its exports. Such a case never did, and never will occur. A nation which is in want of money, must also be in want of other commodities; for men only desire money, because of its being the readiest means of increasing their command over the necessaries and enjoyments of life. The extreme variety, too, in the soil and climate, in the powers and perfection of the machinery, and in the skill and industry of the artisans belonging to different countries, must always occasion a considerable difference in the real price of their commodities. But until the cost of production shall have been equalized, there must always be a demand in one country for those commodities which can be produced cheaper in another; and until the desire to accumulate shall be banished from the human breast, there must always be an inclination to import commodities from those countries, where their exchangeable value is least to where it is greatest.

3. In treating of the *nominal* exchange, we endeavoured to show, that it is impossible that any country should be able, for any length of time, to import or export a greater quantity of bullion, than would be necessary to preserve the value of bullion in that country, in its proper relation to the value of bullion in other countries; or, which is the same thing, to have the *real* exchange either highly favourable or unfavourable. But although this principle is strictly true in reference to its *aggregate* exchanges, it is incorrect when the state of its exchange with one country only is considered. Great Britain, for example, may constantly have the exchange in her favour with Portugal, provided she has it constantly, and to an equal extent, against her with the East Indies, or some other country. "She may," to use the words of Mr Ricardo, "be importing from the north the bullion which she is exporting to the south. She may be collecting it from countries, where it is relatively abundant, for others, where it is relatively scarce, or where, from some particular causes, it is in great demand. Spain, who is the great importer of bullion from America, can never have an unfavourable exchange with her colonies; and as she must distribute the bullion she receives among the different nations of the world, she can seldom have a favourable exchange with the countries with which she trades."*

It was by this principle that Lord King ingeniously, and, we think, successfully accounted for the nearly continued favourable exchange between this country and Hamburgh, from 1770 to 1799. His Lordship showed that the importation of bullion from Hamburgh and other countries was only equivalent to the quantity exported to the East Indies, and consumed at home; that the demand corresponded to the supply, and consequently that its relative value remained stationary. The extraordinary influx of bullion into this country from the Continent at the era of the restriction, and the very favourable state of the exchange, was undoubtedly owing, in a very great degree, to the then reduction in the issues of Bank paper, and to the diminution of the gold currency caused by the hoarding of guineas, &c. In 1797 and 1798, above *five* millions of guineas were coined at the mint; and this extraordinary demand for gold is of itself abundantly sufficient to account for the very favourable exchange of that period, and for the length of time which it continued. But, at the same time that the demand for *gold* bullion for the mint had been thus increased, the demand for *silver* bullion, for the purpose of exportation by the East India Company, had also been proportionably augmented. In 1795, the quantity exported on account of the Company, and of private persons, amounted to only . . . 151,795 ounces.
In 1796, to . . . 290,777
1797, . . 962,880
1798, . . 3,565,691
1799, . . 7,287,327

From this period, the exportation of silver to the East Indies was very much reduced; and, in the years in which the exchange was most unfavourable, it had almost entirely ceased.

Instead, therefore, of the extraordinary importation of bullion from Hamburgh in 1797 and 1798 affording, as Mr Bosanquet and others have supposed, a practical proof of the fallacy of the opinion of those who contend that it is impossible, for any length of time, to destroy the natural equilibrium in the value of bullion in different countries, it is in itself a striking example of its truth. Without this influx of bullion, its value, in this country, could not have maintained its proper relation to its value in other countries. We imported bullion, because, owing to the reduction of our paper currency, and the increased demand by the East India Company, its value was rendered higher here than in the Continent; and, consequently, because the Continental merchants found it advantageous to send bullion to this country, in the same manner as they would have sent corn, or any other commodity for which there was an unusual demand in Great Britain. For, however favourable the *real* exchange between Hamburgh and London might have been to the latter, we should not have imported a single ounce of bullion had it not been, at the time, the most advantageous article with which Hamburgh could discharge its debt to London.

---

* See *Reply to Mr Bosanquet's Observations on the Report of the Bullion Committee,* p. 17,—one of the best pamphlets that has ever been published on the subject of Exchange.

4. In the absence of all other arguments, it would be sufficient to state, that it is physically impossible the excess of exports over imports, as indicated by the Customhouse Returns, can be paid in bullion. Every country in the world, with the single exception of the United States, has its favourable balance; and, of course, they must be paid by an annual influx of bullion from the mines corresponding to their *aggregate* amount. It is certain, however, that the entire produce of the mines, though it were increased in a *tenfold* proportion, would be insufficient for this purpose! This, of itself, is decisive of the degree of credit which ought to be attached to the commonly received opinions on this subject.

5. In the last place, the profit on our transactions with foreigners consists not in the quantity of bullion imported from abroad; but in "the excess of the value of the entire imports over the value of the entire exports." If in return for an exportation of commodities worth *ten* or *twenty* millions, we import commodities worth *fifteen* or *thirty*, we shall, provided money has not altered in value, gain 50 *per cent.* by the transaction, and that although the exports should have consisted entirely of bullion, and the imports of corn, sugar, coffee, &c. It is a ridiculous prejudice that would induce us to import bullion rather than any other commodity. But whatever the partisans of the exclusive system may say about its being a *preferable product*, a *marchandise par excellence*, we may be assured that it will never appear in the list of exports or imports, while there is any other commodity whatever with which to carry on trade that will yield a larger profit.

Thus it appears, that the excess of exports over imports, instead of being any proof of an advantageous commerce, is distinctly and completely the reverse;—that a commercial country may, and almost always does, import commodities of a greater value than it exports, without rendering itself indebted to foreigners:—And that, when a balance of debt has been contracted, that is, when the sum *payable to* foreigners for the commodities imported from abroad is greater than the sum *receivable from* them for the commodities they export, the balance will not be paid by an exportation of bullion from the debtor to the creditor country, unless bullion be the most profitable article of export.

Effect of fluctuations in the Real Exchange on Foreign Trade.

We have, in the previous *section*, shown that fluctuations in the nominal exchange have no effect on foreign trade. When the currency is depreciated, the premium which the exporter of commodities derives from the sale of the bill drawn on his correspondent abroad, is only equivalent to the increase in the price of the goods exported, occasioned by this depreciation. But when the premium on a foreign bill is a consequence not of a fall in the value of money, but of a deficiency in the supply of bills, there is no rise of prices; and in these circumstances the unfavourable exchange undoubtedly operates as a stimulus to exportation. As soon as the *real* exchange diverges from *par*, the mere inspection of a price current is no longer sufficient to regulate the operations of the merchant. If it is unfavourable, the premium which the exporter will receive on the sale of his bill must be included in the estimate of the profit he is likely to derive from the transaction. The greater that premium the less will be the difference of prices necessary to induce him to export. And hence an unfavourable *real* exchange has an effect exactly the same with what would be produced by granting a bounty on exportation equal to the premium on foreign bills.

But for the same reason that an unfavourable *real* exchange increases exportation, it must proportionably diminish importation. When the exchange is really unfavourable, the price of commodities imported from abroad must be so much lower than their price at home, as not merely to afford, exclusive of expences, the ordinary profit of stock on their sale, but also to compensate for the premium which the importer must pay for a foreign bill if he remits one to his correspondent, or for the discount, added to the invoice price, if his correspondent draws upon him. A much less quantity of foreign goods will, therefore, suit our market when the *real* exchange is unfavourable, and fewer payments having to be made abroad, the competition for foreign bills will be diminished, and the *real* exchange rendered proportionably favourable. In the same way, it is easy to see, that a favourable *real* exchange must operate as *duty* on exportation, and as a *bounty* on importation.

It is thus that fluctuations in the *real* exchange have a necessary tendency to correct themselves. They can never, for any considerable period, *exceed* the expence of transmitting bullion from the debtor to the creditor country. But the exchange cannot continue either permanently favourable or unfavourable to this extent. When favourable, it corrects itself by restricting exportation and facilitating importation, and when unfavourable, it produces the same effect by giving an unusual stimulus to exportation, and by throwing obstacles in the way of importation. The true PAR forms the centre of these oscillations, and although the thousand circumstances which are daily and hourly affecting the state of debt and credit, prevent the ordinary course of exchange from being almost ever precisely at *par*, its fluctuations, whether on the one side or the other, are confined within certain limits, and have a constant tendency to disappear.

This natural tendency which the exchange has to correct itself, is powerfully assisted by the operations of the bill merchants.

The operations of the Bill Merchants have a tendency to lessen Fluctuations in the *real* Exchange.

England, for example, might owe a large excess of debt to Amsterdam, yet, as the aggregate amount of the debts *due* by a commercial country, is generally balanced by the amount of those which it has to receive, the deficiency of bills on Amsterdam in London would most probably be compensated by a proportionable redundancy of them in some other quarter. Now, it is the business of the merchants who deal in bills, in the same way as of those who deal in bullion or any other commodity, to buy them where they are cheapest, and to sell them where they are dearest. They would, therefore, buy up the bills drawn by other countries on Amsterdam, and dispose of them in London; and by so doing, would prevent any great fall in the price of bills on Amsterdam in those countries in which the supply exceeded the demand, and any great rise in Great Britain and those countries in which the supply happened to be deficient. In the trade between Italy and this country, the bills drawn on Great Britain amount almost invariably to a greater sum than those drawn on Italy. The bill merchants, however, by buying up the excess of the Italian bills on London, and selling them in France, Holland, and other countries indebted to England, prevent the *real* exchange from ever becoming very much depressed.

A large Foreign Expenditure has no permanent effect on the Exchange.

An unusual deficiency in the supply of corn, or of any other article of prime necessity, the demand for which could not be immediately contracted, by causing a sudden augmentation of the imports from abroad, must always materially affect the state of debt and credit with foreign countries, and depress the exchange. In time of war the balance of payments is liable to be still further deranged; the amount of the bills drawn on a country carrying on foreign hostilities, being increased by the whole expence of the armaments abroad and of subsidies to foreign powers. But neither the conjoined nor separate influence of both or either of these causes, can exert any permanent influence on the exchange. A sudden increase in the accustomed supply of bills, must, in the first instance, by glutting the market, occasion their selling at a discount; but this effect can only be of a very temporary duration. The unusual facilities which are then afforded for the exportation of manufactured produce to the foreign market, and the difficulties which are thrown in the way of importation, never fail speedily to bring the *real* exchange to *par*.

In a period of profound peace we may, by exporting an excess of raw or manufactured produce, overload the foreign market, and occasion such a decline in the price of British goods abroad, as to render the imported less valuable than the exported commodities with which they have been purchased. But such a state of things must speedily operate its own cure. The distress which it necessarily occasions would lead to an immediate diminution of exports; and the supply of British commodities in the foreign market being thus rendered more nearly commensurate with the demand, they would, of course, sell for an adequate profit, and, in consequence, the entire value of the imports would again exceed, as it always ought to do, the entire value of the exports. But whenever a country has a large foreign expenditure to sustain, its exports must be proportionably augmented. Such an expenditure can only be discharged either by the Government directly sending abroad an equivalent amount of commodities, or by means of bills of exchange drawn on account of produce exported by private individuals. Supposing the foreign expenditure of Great Britain during the late war to have amounted to ten or twenty millions a-year, it is evident we must have annually exported an equal amount of the produce of our land, capital, and labour, for which payment would be received, not, as in ordinary cases, by a corresponding importation of foreign commodities, but from the treasury at home. This is strictly true, even though it were admitted that the expenditure had, in the first instance, been entirely discharged by remittances of bullion; for the increased supply of bullion which would thus have been required, could only have been obtained by an equally increased exportation of other produce to the countries possessed of mines, or from which it could be advantageously imported. Foreign expenditure increases the amount of the exports precisely in proportion to its own amount, and is therefore incapable of exerting any permanent effect on the exchange.

Thus, it appears that a great excess of exports, instead of being any criterion of increasing wealth at home, is only a certain indication of great expenditure abroad. "When," says Mr Wheatley, "the exports exceed the imports, as they must do when there is a large foreign expenditure, the equivalents for the excess are received abroad in as full and ample a manner as if the produce which they purchased were actually imported and entered in the customhouse books, and afterwards sent to the seat of war for consumption. But from the circumstance of its not being inserted in the customhouse entries as value received against the produce exported for its payment, the latter is deemed to constitute a favourable balance, when it is in reality exported to liquidate a balance against us." (Wheatley *On the Theory of Money*, p. 219.)

Cause of the Rise of the Exchange in 1815 and 1816.

But however conclusive this reasoning may appear, it has, nevertheless, been strenuously contended that it is at *variance with the fact*; and that the rise of the exchange in autumn 1814, and its restoration to *par* in 1816, when the restriction on cash payments was in full operation, is a practical and convincing proof that its previous depression had been a consequence not of the depreciation of the currency, but of the excessive supply of bills on London in the foreign market, occasioned by the expensive contest in which we were then engaged. According to our view of the matter, however, this fact leads to a precisely opposite conclusion. It is of no use to tell us that the exchange came to *par*, while the restriction act was unrepealed. It was never contended, that the simple fact of such a law being in existence, could have any effect in depreciating the currency. The restriction was condemned, and justly condemned, because it *enabled* the Bank of England to deluge the country with paper. If the Bank had never abused that power,—if the proprietors had sacrificed their own direct, palpable, and individual interests to those of the public, and had constantly kept their paper on a level with bullion, the restriction act, though unwise, would, as to consequences, have been the same as if it had never existed. The question is not, therefore, whether the exchange came to *par* while the restriction continued but *whether it came to* PAR, *while as many notes circulated as in the period of its greatest depression?* If this could be shown, and if it could also be shown that the effective demand for paper had not, at the same time, been proportionably increased, the argument would be conclusive; and we should be compelled to admit that a great comparative increase of paper money has no tendency to diminish its value, or to render the *nominal* exchange unfavourable.

But it would be worse than idle to set about proving by argument a fact so notorious as the prodigious diminution of bank paper in 1814, 1815, and 1816. In that period above 240 country banks became altogether bankrupt, or at least stopped payments; and the issues of the remainder were very much diminished. The Board of Agriculture estimated, that, in the county of Lincoln alone, above *three* millions of bank paper had been withdrawn from circulation; and the total diminution of the currency during the three years in question has seldom been estimated at less than *sixteen* or *twenty* millions, though it probably amounted to a great deal more. Mr Horner, the accuracy and extent of whose information cannot be called in question, made the following statement on this subject, in his place in Parliament:

" From inquiries he had made, and from the accounts on the table, he was convinced that *a greater and more sudden reduction of the circulating medium had never taken place in any country than had taken place since the peace in this country*, with the exception of those reductions that had taken place in France after the Mississippi scheme, and after the destruction of the assignats. The reduction of the currency had originated in the previous fall of the prices of agricultural produce. That fall had produced a destruction of country-bank paper, to an extent which would not have been thought possible, without more ruin than had actually ensued. The Bank of England had also restricted its issues. As appeared by the accounts recently presented, the average amount of its currency was not, during the last year, more than between L.25,000,000 and L.26,000,000; while two years ago it had been nearer L.29,000,000, and at one time even amounted to L.31,000,000. But without looking to the diminution of Bank of England paper, the reduction of the country paper was enough to account for the rise which had taken place in the exchange."

Here, then, is the true cause of the exchange coming to *par* in 1815 and 1816. It had nothing to do with the cessation of hostilities, but was entirely a consequence of the increased value of our currency, caused by the sudden reduction of its quantity. Instead, therefore, of being at variance with the principles we have been endeavouring to elucidate, this fact affords the strongest possible confirmation of their perfect correctness. And having been sanctioned by the fullest experience, they may now be considered as placed beyond the reach of cavil and dispute.

An objection of a different sort has been made by a very able economist to another part of the theory maintained in this *section*, of which it will here be proper to take some notice.

Refutation of the opinion, that, during an unfavourable real Exchange, Commodities of great value and small bulk are exported in preference to others.

When the exchange becomes unfavourable, the premium, procured by the sale of the bill drawn on a foreign merchant to whom bullion has been consigned, is no greater than would have been obtained by consigning to him a quantity of coffee, tea, sugar, indigo, &c., of equal value. An unfavourable *real* exchange will permit a merchant to export commodities which could not be exported were the *real* exchange at *par*, or favourable; but the advantage still remains of exporting those commodities in preference, whose price in the country from which they are exported, compared with their price in the country into which they are imported, is lowest. Suppose, for example, that the expence of transmitting bullion from this country to France is *three per cent.* that the *real* exchange is *four per cent.* against us, that the price of bullion is the *same* in both countries, and that coffee, exclusive of the expences of carriage, is really worth *four per cent.* more in France than in England. In such a case, it is obvious, the exporter of bullion would realize only a profit of *one per cent.*, while the exporters of coffee would realize, inclusive of the premium on the sale of the foreign bill, a profit of *seven per cent.* And hence the opinion maintained by Colonel Torrens (*Comparative Estimate, &c.*), that when the exchange becomes unfavourable, those commodities which contain the greatest value in the smallest bulk, or on which the expence of carriage is least, would be exported in preference, appears to rest on no good foundation. The relative value of the commodities which nations trading together are in the habit of exporting and importing, is regulated not merely by the cost of their production, but also by the expence necessarily incurred in carrying them from where they are produced to where they are consumed. If Great Britain were in the constant habit of supplying France with corn and bullion, the average price of corn in France, because of the expence required to convey it to this country, would plainly be from 10 to 15 *per cent.* higher than in Britain, while, because of the comparative facility with which bullion might be transported from the one to the other, its value in Paris would not exceed its value in London more than 2 or 3 *per cent.* Now, supposing, that when the prices of both corn and bullion in Great Britain and France are adjusted according to their natural proportions, the *real* exchange becomes unfavourable to this country, it is clear, that this fall in the exchange can give no advantage to the exporters of bullion more than it gives to the exporters of corn. The rise in the price of foreign bills does not increase the expence attending the exportation either of corn or bullion. It leaves the cost of production and of the transportation of those commodities between the two countries exactly where it found them. During the depression of the exchange, the exporter of bullion, equally with the exporter of corn, will derive a premium from the sale of the bill drawn on his correspondent abroad. But there can be no possible inducement to export bullion in preference to corn, unless the real price of bullion should increase more rapidly in France, or decline more rapidly in Great Britain, than the real price of corn.

Whatever, therefore, may be the depression of the exchange, the merchant, as in every other case, selects those commodities for exportation, which will, exclusive of the premium, yield the greatest profit on their sale. If bullion is one of these commodities, it will, of course, be exported, if not, not. Bullion, however, is of all other commodities that of which the relative value approaches nearest to an equilibrium in different countries, and hence it is the least likely to be exported during an unfavourable exchange. The demand for bullion is comparatively steady, and no great surplus quantity could be imported into one country without reducing its value, or exported from another without raising its value, so as to unfit it either for exportation or importation. A very small part only of an unfavourable balance is ever paid in bullion. The operations of the bullion merchant are chiefly confined to the distribution of the fresh supplies which are annually dug from the mines proportionably to the effective demand of different countries. Its price is too invariable, or, which is the same thing, its supply and demand are too constant, to admit of its ever becoming an important article in the trade between any two countries, neither of which are in possession of mines.

In corroboration of this argument, we may mention that, according to the official statement laid on the table of the House of Commons, it appears that the expences incurred by this country on account of the armies acting in Portugal and Spain during the following years, were as under:

In 1808,	L.2,903,540
9,	2,450,956
10,	6,066,021
11,	8,906,700
12, 13,	31,767,794
14,	13,—,—

Of which, according to the same official statement, only the following sums were remitted in coin or bullion:

In 1808,	L.2,861,339
9,	461,926
10,	697,675
11,	748,053
12, 13,	3,284,435

Of the sum of *five* millions voted to our allies in 1813 and 1814, not more than L.300,000 was sent in bullion, the rest being made up by the exportation of manufactured goods and military stores. (*Edinburgh Review*, Vol. XXVI. p. 154.) The high market price of gold and silver in 1809, 1810, &c. could not, therefore, be owing to the purchases made by Government, for they were not greater than the sums exported by the East India Company in 1798 and 1799, and in 1803, 1804, and 1805, when there was scarcely any perceptible rise in the price of bullion. The immense additions made to the paper currency of the country in 1809, 1810, &c. sunk its value compared with bullion, and was the true cause of the unfavourable *nominal* exchange of that period.

SECTION III.—*Computed Exchange.*

Computed Exchange.

Having thus endeavoured to point out the manner in which variations in the comparative value of the currencies of nations trading together, and in the supply and demand for bills, separately affect the exchange, it now only remains to ascertain their combined effect. It is on this that the *computed*, or actual course of exchange depends.

The computed Exchange represents either the *sum* or the *difference* of the real and nominal Exchange.

From what we have already stated, it must be obvious, that when the nominal and real exchange are both favourable, or both unfavourable, the *computed* exchange will express their *sum;* and that when the one is favourable and the other unfavourable, it will express their *difference*.

When, for example, the currency of Great Britain is of the mint standard and purity, and the currency of France 5 *per cent.* degraded, the *nominal* exchange will be 5 *per cent.* in favour of this country. But the *real* exchange may, at the same time, be either favourable or unfavourable. If it be also favourable to the extent of 1, 2, 3, &c. *per cent.* the computed exchange will be 6, 7, 8, &c. *per cent.* in favour of this country. And, on the other hand, if it is unfavourable to the extent of 1, 2, 3, &c. *per cent.* the *computed* exchange will be only 4, 3, 2, &c. *per cent.* in our favour. When the *real* exchange is in favour of a particular country, provided the *nominal* exchange be equally against it, the *computed* exchange will be at *par*, and *vice versa*.

A comparison of the market with the mint price of bullion, affords the best criterion whereby to ascertain the state of the exchange at any particular period. When no restrictions are imposed on the trade in the precious metals, the excess of the market over the mint price of bullion, affords a pretty accurate measure of the depreciation of the currency. If the market and mint price of bullion at Paris and London exactly corresponded, and if the value of bullion was the same in both countries, the *nominal* exchange would be at *par;* and whatever fluctuations the computed exchange might exhibit, must be traced to fluctuations in the *real* exchange, or which is the same thing, in the supply and demand for bills. If, when the market price of bullion in Paris is equal to its mint price, it exceeds it 10 *per cent.* in London, it is a proof that our currency is 10 *per cent.* depreciated, and consequently the *nominal* exchange between Paris and London *must* be 10 *per* *cent.* against the latter. Instead, however of the *computed*, or actual course of exchange, being 10 *per cent.* against London, it may either be against it to a greater or less extent, or in its favour. It will be more against it provided the *real* exchange is also unfavourable,—it will be less against it provided the *real* exchange be in favour of London, though to a less extent than the adverse *nominal* exchange,—and it will be in favour of London, should the favourable *real* exceed the unfavourable *nominal* exchange. Thus, if while the value of British was 10 *per cent.* less than the value of French currency, the *computed* or actual course of exchange between Paris and London was 12 or 15 *per cent.* against the latter, it would show that the *real* exchange was also against this country to the extent of 2 or 3 *per cent.* And if, on the other hand, the computed exchange was only 5 or 6 *per cent.* against London, it would show that the *real* exchange was 4 or 5 *per cent.* in its favour, and so on.

It has already been shown, that, in so far, at least, as the question of exchange is involved, the differences between the value of bullion in different countries are limited by the expence of transit from the one to the other. And hence, by ascertaining whether a particular country is in the habit of exporting or importing bullion to or from other countries, we are enabled to determine its comparative value in these countries. Supposing, for example, that the expence of conveying bullion from this country to France, including the profits of the bullion dealer, is equivalent to 2 *per cent.*, it is clear, inasmuch as bullion is only exported *to find its level*, that whenever our merchants begin to export bullion to France, its value there must be 2 *per cent.* greater than in England; and, on the contrary, when they import bullion from France, its value in this country must be 2 *per cent.* greater than its value in France. In judging of the state of the exchange between any two countries, this circumstance must always be attended to. If no bullion be passing from the one to the other, we may conclude that its value is nearly the same in both countries; at all events, it is certain that the difference of its value is *less* than the expence of transit. On the supposition, that the entire expence, including profit, &c. of conveying bullion from Rio Janeiro to London is 5 *per cent.*, and that the London merchants are importing bullion, then it is clear, provided the real exchange is at *par*, and that the currency of both cities is at the Mint standard, that the *nominal*, or which, in this case, is the same thing, the *computed* exchange will be 5 *per cent.* in favour of London. But if the currency of London is 5 *per cent.* depreciated, or, in other words, if the market price of bullion at London is 5 *per cent.* above its mint price, the *computed* exchange between it and Rio Janeiro, supposing the *real* exchange to continue at *par*, will obviously also be at *par*. It may, therefore, be laid down as a general rule, that as soon as bullion begins to pass from one country to another, *the expence of transit*, provided the mint and market price of bullion in the *exporting* country correspond, will indicate how much the value of its bullion falls short of the value of bullion in the country into which it is imported; or, which is the same thing, will be equal to its unfavourable *nominal* exchange; and that, when the market exceeds the mint price of bullion in the *exporting* country, the expence of transit, *added* to this excess, will give the total comparative reduction of the value of the precious metals in that country. The converse of this takes place in the country *importing* bullion. When its currency is of the mint standard, the expence of transit measures the extent of its favourable *nominal* exchange; but when its currency is relatively redundant or degraded, the *difference* between the expence of transit and the excess of the market above the mint price of bullion, will measure the extent of the favourable or unfavourable *nominal* exchange.—It will be favourable when the depreciation is less than the expense of transit, and unfavourable when it is greater.

State of the Exchange between Great Britain and the Continent, from 1809 to 1815.

From 1809 to 1815 inclusive, Great Britain continued to export gold and silver to the Continent. During this period, therefore, we must add the expences attending its transit to the excess of the market over the mint price of bullion, in order to ascertain the true relative value of British currency, and the state of the *real* exchange. Mr Goldsmid stated to the Bullion Committee that, during the last five or six months of the year 1809, the expence of transporting gold to Holland and Hamburgh, inclusive of freight, insurance, exporter's profits, &c. varied from 4 to 7 *per cent.* But, at the same time that the relative value of bullion in Britain was at 5½ (medium of 4 and 7) *per cent.* below its value in Hamburgh, the market price of gold bullion exceeded its mint price to the extent of 16 or 20 *per cent.* or 18 *per cent.* on a medium; so that the currency of this country, as compared with the currency of Hamburgh, which differed very little from its mint standard, was really depreciated to the extent of 23½ *per cent.* Now, as it appears from the tables annexed to this article, that the *computed* or actual course of exchange varied, during the same period, from 19 to 21 *per cent.* against London, it is clear that the *real* exchange could not be very different from *par*. Had the *computed* exchange been less unfavourable, it would have shown that the *real* exchange was in favour of London; had it been more unfavourable, it would, on the contrary, have shown that the *real* exchange was decidedly against London.

Causes of the Exportation of Bullion in 1809, 1810, &c.

Provided an accurate account could be obtained of the expence attending the transit of bullion from this country to the Continent during the subsequent years of the war, we have no doubt it would be found, notwithstanding the extraordinary depression of the *nominal*, that the *real* exchange fluctuated very little from *par;* and that the exportation of gold and silver was a consequence, not of the balance of payments being against this country, but of its being advantageous to export bullion, because of its being less valuable here than on the Continent. No person will contend that, in 1809, 1810, &c. there was such a redundancy of gold or silver currency in this country as to sink the relative value of these metals. Any such supposition is altogether out of the question. During the period referred to, the precious metals were sent out of the country, because the depreciation of the paper currency exceeded the cost of the transit of bullion; and hence, because it was every body's interest to pay their debts in the depreciated currency, and to export that which was undepreciated to other countries where there was no law to prevent its passing at its full value as coin, or in which there was a greater demand for bullion. It is indisputably certain that, if our *paper-currency* had been sufficiently reduced, the supply of gold in the kingdom in 1809, 1810, &c. compared with the demand which must, in such circumstances, have been experienced, was so very small, that, instead of exporting, we should have imported the precious metals from every country in the world.

The unfavourable Exchange during the latter years of the War, no cause of the extraordinary Exportation of British produce to the Continent.

It has been very generally supposed, that the extraordinary exportation of British goods to the Continent during the latter years of the war, was in a great measure owing to the depression of the exchange. But, in so far as this depression was occasioned by the redundancy, or depreciation, of the currency, it could have no such effect. It is impossible, indeed, to form any opinion as to the influence of fluctuations in the *computed* exchange on export and import trade, without having previously ascertained whether they are a consequence of fluctuations in the *real* or *nominal* exchange. It is only by an unfavourable *real* exchange that exportation is facilitated; and it may be favourable at the very moment that the *computed* exchange is decidedly unfavourable. "Suppose," to use an example given by Mr Blake, "the computed exchange between Hamburgh and London, to be 1 *per cent.* against this country, and that this arises from a *real* exchange which is favourable to the amount of 4 *per cent.*, and a nominal exchange unfavourable to the extent of 5 *per cent.*; let the real price of bullion at Hamburgh and London be precisely the same, and, consequently, the *nominal* prices different by the amount of the *nominal* exchange, or 5 *per cent.*; now, if the expences of freight, insurance, &c. on the transit of bullion from Hamburgh are 3 *per cent.*, it is evident that a profit would be derived from the import of that article, notwithstanding the *computed* exchange was 1 *per cent.* against us. In this case, the merchant must give a premium of 1 *per cent.* for the foreign bill to pay for the bullion;—L.100 worth of bullion at Hamburgh would therefore cost him L.101, and the charges of importation would increase the sum to L.104. Upon the subsequent sale, then, for L.105 of depreciated currency in the home market, he would derive from the transaction a profit of L.1. This sum is precisely the difference between the *real* exchange and the expences of transit, that part of the *computed* exchange which depends on the *nominal*, producing no effect; since whatever is lost by its unfavourable state, is counterbalanced by a corresponding inequality of *nominal* prices." (*Observations*, *&c.* p. 91.) In the same manner, it may be shown, that, notwithstanding the *computed* being favourable, the *real* exchange may be unfavourable; and that, consequently, it might be really advantageous to export, when it was apparently advantageous to import. But it would be tedious to multiply instances, which, as the intelligent reader will readily conceive, may be infinitely varied, and which have been sufficiently explained in the foregoing sections.

The real cause of the extraordinary importation of British produce into the Continent in 1809, 1810, &c., notwithstanding the anticommercial system of Bonaparte, is to be found, not in the state of the exchange; for, inasmuch as that was occasioned by a fall in the value of the currency, it could have no effect whatever either in increasing or diminishing exportation; but in the annihilation of the neutral trade, and our monopoly of the commerce of the world. The entire produce of the East and of the West was placed at our sole disposal. The Continental nations could neither procure colonial produce, nor raw cotton for the purposes of manufacturing, except directly from England. British merchandise was thus rendered almost indispensable; and to this, our immense exportation, in spite of all prohibitions to the contrary, is to be ascribed.—(See *Edinburgh Review*, No. LXIII. p. 50.)

Negociation of Bills of Exchange.

Manner of negociating Bills of Exchange.

In conducting the business of exchange a direct remittance is not always preferred. When a merchant in London, for example, means to discharge a debt due by him in Paris, it is his business to ascertain, not only the state of the direct exchange between London and Paris, and, consequently, the sum which he must pay in London for a bill on Paris equivalent to his debt, but also the state of the exchange between London and Hamburgh, Hamburgh and Paris, &c.; for it frequently happens, that it will be more advantageous for him to buy a bill on Hamburgh, Amsterdam, or Lisbon, and to direct his agent to invest the proceeds in a bill on Paris, rather than remit directly to the latter. This is termed the ARBITRATION of exchange. An example or two will suffice to show the principle on which it is conducted.

Arbitration of Exchange.

Thus, if the exchange between London and Amsterdam be 35s. Flemish *per* pound Sterling, and between Paris and Amsterdam 1s. 6d. Flemish *per* franc, then, in order to ascertain whether a direct or indirect remittance to Paris would be most advantageous, we must calculate what would be the value of the franc in English money if the remittance were made through Holland; for if it be less than that resulting from the direct exchange, it will obviously be the preferable mode of remitting. This is determined by stating, as 35s. Flem. (the Amsterdam currency in a pound Sterling): 1s. 6d. Flem. (Amsterdam currency in a franc) : : L.1 : 10d. the proportional, or *arbitrated* value of the franc.—Hence if the English money, or bill of exchange, to pay a debt in Paris were remitted by Amsterdam, it would require 10d. to discharge a debt of a franc, or L.1 to discharge a debt of 24 francs: And, therefore, if the exchange between London and Paris was at 24, it would be indifferent to the English merchant whether he remitted directly to Paris, or indirectly *via* Amsterdam; but if the exchange between London and Paris was *above* 24, then a direct remittance would be preferable; while, if, on the other hand, the direct exchange was less than

24, the indirect remittance ought as plainly to be preferred.

"Suppose," to borrow an example from Dr. Kelly (*Universal Cambist*, Vol. II. p. 137), "the exchange of London and Lisbon to be at 68d. *per* milree, and that of Lisbon on Madrid 500 rees *per* dollar, the arbitrated price between London and Madrid is 34d. Sterling *per* dollar; for as 1000 rees : 68d. : : 500 rees to : 34d. But if the direct exchange of London on Madrid be 35d. Sterling *per* dollar, then London, by remitting directly to Madrid, must pay 35d. for every dollar; whereas, by remitting through Lisbon, he will pay only 34d.; it is, therefore, the interest of London to remit indirectly to Madrid through Lisbon. On the other hand, if London draws directly on Madrid, he will receive 35d. Sterling *per* dollar; whereas, by drawing indirectly through Lisbon, he would receive only 34d.; it is, therefore, the interest of London to draw directly on Madrid. Hence the following rules:

1. Where the *certain price* is given, draw through the place which produces the lowest arbitrated price, and remit through that which produces the highest.

2. Where the *uncertain price* is given, draw through that place which produces the highest arbitrated price, and remit through that which produces the lowest."

In Compound Arbitration, or when more than *three* places are concerned, then, in order to find how much a remittance passing through them all will amount to in the last place, or, which is the same thing, to find the arbitrated price between the first and the last, we have only to repeat the different statements in the same manner as in the foregoing examples.

Thus, if the exchange between London and Amsterdam be 35s. Flem. for L.1 Sterling; between Amsterdam and Lisbon 42d. Flem. for 1 old crusade; and between Lisbon and Paris 480 rees for 3 francs, What is the arbitrated price between London and Paris?

In the first place, as 35s. Flem. : L.1 : : 42d. Flem. : 2s. Sterling, = 1 old Crusade.

Second, as 1 old Crusade, or 400 rees : 2s. Sterling : : 480 rees : 2s. 4⅘d Sterling, = 3 francs.

Third, as 2s. 4⅘d. Sterling : 3 francs : : L.1 Sterling : 25 francs, the arbitrated price of the pound Sterling between London and Paris.

This operation may be abridged as follows:

		L.1 Sterling.
L.1 Sterling	=	35s. Flemish.
3½ shillings Flem.	=	1 old Crusade.
1 old Crusade		400 Rees.
480 Rees		3 Francs.

$$\text{Hence}\cdot\frac{35\times 400\times}{480\times 3\frac{1}{2}}=\frac{4200}{168}=25\text{ francs.}$$

This abridged operation evidently consists in arranging the terms, so that those which would form the divisors in continued statements in the *Rule of Three* are multiplied together for a common divisor, and the other terms for a common dividend. The ordinary arithmetical books abound with examples of such operations.

The following account of the manner in which a very large transaction was actually conducted, by indirect remittances, will sufficiently illustrate the principles we have been endeavouring to explain.

In 1804, Spain was bound to pay to France a large subsidy; and, in order to do this, three distinct methods presented themselves:

1. To send dollars to Paris by land.
2. To remit bills of exchange directly to Paris.
3. To authorise Paris to draw directly on Spain.

The first of these methods was tried; but it was found too slow and expensive; and the second and third plans were considered likely to turn the exchange against Spain. The following method by the indirect, or circular exchange, was therefore adopted:

A merchant, or *banquier*, at Paris, was appointed to manage the operation, which he thus conducted: He chose London, Amsterdam, Hamburgh, Cadiz, Madrid, and Paris, as the principal hinges on which the operation was to turn; and he engaged correspondents in each of these cities to support the circulation. Madrid and Cadiz were the places in Spain from whence remittances were to be made; and dollars were, of course, to be sent to where they bore the highest price, for which bills were to be procured on Paris, or on any other places that might be deemed more advantageous.

The principle being thus established, it only remained to regulate the extent of the operation, so as not to issue too much paper on Spain, and to give the circulation as much support as possible from real business. With this view, London was chosen as a place to which the operation might be chiefly directed, as the price of dollars was then high in England, a circumstance which rendered the proportional exchange advantageous to Spain.

The business was commenced at Paris, where the negociation of drafts issued on Hamburgh and Amsterdam served to answer the immediate demands of the state; and orders were transmitted to these places to draw for the reimbursements on London, Madrid, or Cadiz, according as the course of exchange was most favourable. The proceedings were all conducted with judgment, and attended with complete success. At the commencement of the operation, the course of exchange of Cadiz on London was 36d.; but, by the plan adopted, Spain got 39¼d., or above 8 *per cent.* by the remittance of dollars to London and considerable advantages were also gained by the circulation of bills through the several places on the Continent.*

Usance Days of Grace.

Bills of exchange are either made payable at *sight*;—at a certain specified time *after sight*, or *after date*;—or at *usance*, which is the usual term allowed by the custom or law of the place where the bill is payable. Generally, however, a few days are allowed for payment beyond the term when the bill becomes due, which are denominated *days of grace*, and which vary in different countries. In Great Britain and Ireland, *three* days of grace are allowed for all bills except those payable at sight, which must be paid as soon as presented.

The following is a statement of the *usance* and

---

* Kelly's *Cambist*, Vol. II. p. 168; Dobost's *Elements of Commerce*, 2d edit. p. 218.

days of grace for bills drawn by London on some of the principal commercial cities:

[*m|d. m|s. d|d. d|s. d|a.* respectively denote *months after date, months after sight, days after date, days after sight, days after acceptance.*]

London on	Usance.	Days of Grace.	London on	Usance.	Days of Grace.
Amsterdam	1 m|d.	6	Gibraltar	2 m|s.	14
Rotterdam	1 m|d.	6	Leghorn	3 m|d.	0
Antwerp	1 m|d.	6	Leipsic	14 d|a.	0
Hamburgh	1 m|d.	12	Genoa	3 m|d.	30
Altona	1 m|d.	12	Venice	3 m|d.	6
Dantzic	14 d|a.	10	Vienna †	14 d|a.	3
Paris *	30 d|d.	10	Malta	30 d|d.	13
Bourdeaux	30 d|d.	10	Naples	3 m|d.	3
Bremen	1 m|d.	8	Palermo	3 m|d.	0
Barcelona	60 d|d.	14	Lisbon	30 d|s.	6
Geneva	30 d|d.	5	Oporto	30 d|s.	6
Madrid	2 m|s.	14	Rio Janeiro	30 d|d.	6
Cadiz	60 d|d.	6	Dublin	21 d|s.	3
Bilboa	2 m|d.	14	Cork	21 d|s.	3

In the dating of bills the new style is now used in every country in Europe, with the exception of Russia.

In London, bills of exchange are bought and sold by brokers, who go round to the principal merchants and discover whether they are buyers or sellers of bills. A few of the brokers of most influence, after ascertaining the state of the relative supply and demand for bills, suggest a price at which the greater part of the transactions of the day are settled, with such deviations, as particular bills, from their being in very high or low credit, may be subject to. The price fixed by the brokers is that which is published in Wettenhall's list; but it is stated by Mr Goldsmid, that the first houses generally negociate their bills on ½, 1, 1½ and 2 *per cent.* better terms than those quoted. In London and other great commercial cities, a class of middlemen speculate largely on the rise and fall of the exchange, buying bills when they expect a rise, and selling them when a fall is anticipated.

History and Advantages of Bills of Exchange.

History and advantages of Bills of Exchange.

It is not easy to discover the precise era when bills of exchange were first employed to transfer and adjust the mutual claims and obligations of merchants. Their invention has been ascribed to the Arabians and the Jews of the middle ages; but it seems certain that bills were in use in remote antiquity. Isocrates states that a stranger who had brought some cargoes of corn to Athens, furnished a merchant of the name of Stratocles with an order, or bill of exchange, on a town on the Pontus Euxinus, where money was owing to him; and, because the person who had drawn the bill had no *fixed domicile*, Stratocles was to have recourse on a merchant in Athens, in the event of its being protested. The merchant, says Isocrates, who procured this order found it extremely advantageous, inasmuch as it enabled him to avoid risking his fortune on seas covered with pirates and the hostile squadrons of the Lacedemonians. (De Pauw, *Recherches sur les Grecs*, I. 258.)

There is also unquestionable evidence to show, that the method of transferring and cancelling the debts of parties, residing at a distance, by means of letters of credit, or, which is the same thing in effect, by means of bills of exchange, was not unknown to the Romans. Cicero, in one of his epistles to Atticus (*Epist. ad Atticum*, XII. 24), inquires whether his son must carry cash to defray the expence of his studies along with him to Athens, or whether he might not save this trouble and expence *by obtaining an assignment for an equivalent sum from a creditor in Rome on his debtor there.* It is evident, from a subsequent epistle of Cicero's, that the latter method had been preferred, and that the transference of the money had in consequence been rendered unnecessary. (*Epist. ad Atticum*, XII. 27.) ‡

Mr Macpherson states (*Annals of Commerce*, I. p. 405.) that the first mention of bills of exchange in modern history, occurs in 1255. The Pope having quarrelled with Manfred King of Sicily, engaged, on Henry III. of England agreeing to indemnify him for the expence, to depose Manfred and raise his second son Edmund to the Sicilian throne. The enterprise misgave. But the merchants of Sienna and Florence who had originally advanced the money to carry it into effect, or rather to gratify the Pope's rapacity, were repaid by bills of exchange drawn on the *Prelates* of England; who, although they protested they knew nothing at all about the transaction, were nevertheless compelled, under pain of excommunication, to pay the bills and *interest!*

Capmany, in his *Memoirs* respecting the Commerce, &c. of Barcelona, gives a copy of an ordonnance of the magistracy, dated in 1394, enacting that bills should be accepted within twenty-four hours after their presentation;—a sufficient proof that they were in general use in the beginning of the fourteenth century.

But whatever may have been the era of the introduction of bills of exchange, it is certain that very few inventions have redounded more to the general advantage. Without this simple and ingenious contrivance, commerce could never have made any considerable progress. Had there been no means of settling and adjusting the mutual claims of debtors and creditors otherwise than by the intervention of metallic money, for bank paper is only another species of bills of exchange, a very great proportion,—many hundreds of millions,—of that capital which is now setting productive labour in motion in every quarter of the globe, and ministering to the comforts, the wants, and the enjoyments of mankind, must have been entirely devoted to the expediting those exchanges which are much better effected by the agency of a few quires of paper. Instead of a perpetual importation and exportation of gold and silver, necessarily attended by an immensity of trouble and expence, a few bills of exchange possessed of almost no intrinsic worth, and which may be transferred with the utmost facility, suffice to balance and adjust the most extensive and complicated transactions. But the mere setting free of an immense reproductive power, which must otherwise have been engaged in a comparatively disadvantageous employment, is only one of the many benefits which, in a commercial point of view, we owe to the use of bills of exchange. By cheapening the instruments with which commerce is carried on, they have materially reduced the price of almost every commodity; and have, in consequence, increased the command of all classes over the necessaries and luxuries of life, and accelerated the progress of civilization, by occasioning a much more extensive intercourse, and intimate connection between different and independent countries than could otherwise have taken place.

---

* In France no days of grace are allowed on bills payable *à vue.*

† In Austria, bills payable at sight, or on demand, or at less than seven days after sight or date, are not allowed any days of grace.

‡ " De Cicerone, ut scribus, ita faciam: ipsi permittam de tempore: nummorum quantum opus erit ut *permutetur* tu videbis." In his notes on a parallel passage, Grævius remarks, *Permutatio* est quod nunc barbare *çambium* dicitur.—(*Epist. ad Atticum*, XI. 24.)

In a political point of view, their effects have been equally salutary. They have enabled every individual imperceptibly to transfer his fortune to other countries, and to preserve it safe alike from the rapacity of his own government, and the hostile attacks of others. The security of property has in this way been prodigiously augmented. And although we should concede to the satirist, that paper credit has "lent corruption lighter wings to fly,"[*] it is easy to show that it has powerfully contributed to render subjects less dependent on the policy, and less liable to be injuriously affected by the injudicious and impolitic measures of their rulers. In countries in a low state of civilization, the inhabitants endeavour, by burying all the gold and silver they can collect, to preserve a part of their property from falling a prey to the extortion of the despots by whom they are alternately plundered and oppressed. This was universally the case in the middle ages; and in Turkey, China, and other Eastern countries, the practice is still carried on to a very great extent. Some political economists have endeavoured to account for the constant importation, and high value of the precious metals in India, from the loss which necessarily attends the practice of hoarding; and undoubtedly this locking up of capital is one of the main causes of the extreme poverty of these countries. But the security derived from bills of exchange is infinitely greater than any that can possibly be derived from the barbarous expedient of trusting property to the bosom of the earth. "Pregnant with thousands flits the *scrap* unseen," and in a moment places the largest fortune beyond the reach of danger! Mr Harris was, therefore, right in stating, "that the introduction of bills of exchange was the greatest security to merchants, both as to their persons and effects, and consequently the greatest encouragement to commerce, and the greatest blow to despotism, of any thing that ever was invented."—(*Harris on Coins*, Part I. p. 108.)

Previous to the peace of Paris in 1763, Amsterdam, because of its commerce, the wealth and punctuality of its merchants, and their intimate connection with all the other great trading cities of the world, was the chief place where the accounts of the different commercial countries were balanced and adjusted. But the entire loss of foreign trade, and the other vexations to which Holland was subjected during the ascendancy of the French, has nearly divested Amsterdam of all share in this business. London has now become the trading metropolis of Europe, and of the world. The vast extent of its commercial dealings has necessarily rendered it the great mart for bills of exchange. Its bill merchants, a class of men remarkable for their shrewdness, and generally possessed of large capitals, assist in trimming and adjusting the balance of debt and credit between the most remote countries. They buy up bills where they are cheap, and sell them where they are dear. And, in consequence of the extent of their correspondence, and the magnitude of their transactions, have given a steadiness to the exchange, to which it could not otherwise have attained.

Laws and Customs respecting Bills and Notes.

Law respecting Bills, &c.

A Bill of Exchange may be defined to be an open letter of request or order from one person, the *drawer*, to another person, the *drawee*, who is thereby desired to pay a sum of money, therein specified, to a third person, the *payee*. When the *drawee* obeys the request or order, by subscribing the document, he becomes *acceptor*. If the contrary do not appear on the face of the bill, it is presumed that the *drawee* has funds of the *drawer's* in his hands to the amount of the bill, and that the drawer is indebted to the *payee* to that extent. The bill thus operates as a transfer, or mercantile assignment to the payee, of the drawee's debt to the drawer. But a bill may also be drawn payable to the *drawer* or his order, in which case, when accepted, the document is not an assignment, but merely the acknowledgment or constitution of a debt. This is also accomplishable by *promissory-note,* which is a promise by one person, the *maker* (Scoticé *Granter*), to pay a certain sum to another person, the *payee* (Scoticé *Grantee*). The bill and the promissory-note have now equally the privilege of being *assignable,* or *transferable* from one person to another by indorsement, that is, by the *payee* subscribing his name on the back of the document. In this case the *payee* becomes an *indorser,* and the person in whose favour the indorsement is made is called the *indorsee,* who may again indorse to another; and in this manner the bill or note may pass from hand to hand without limitation. Each indorsation may be made *in full* or *in blank;* in full, by filling up the name and description of the party in whose favour it is made, which is attended with several advantages if the document should be lost or stolen; in blank, by merely subscribing the indorser's name, which is equivalent to making it payable to the *bearer.* All the indorsements, or any one of them, may also be *qualified* by the words *without recourse,* and when this is done, neither the indorsee nor any subsequent *holder* of the bill or note can have recourse on the indorser who thus qualifies his indorsation. If none of the indorsations be so qualified, the *last holder* for value and *in bona fide,* has all the prior indorsers and other parties to the bill or note bound to him jointly and severally. He may select any one of them, or proceed against them all at the same time; and if all were to become bankrupt, he could claim on the estate of each for the whole debt, and be entitled to receive dividends from all the estates until he obtained *full payment,* but which he must not exceed. An indorser may also qualify his indorsation by the condition that his indorsee shall not have the power of making an indorsement from himself.

---

[*] "Blest paper credit! last and best supply!
That lends corruption lighter wings to fly!
Gold imp'd by thee can compass hardest things,
Can pocket states, can fetch or carry kings;
A single leaf shall waft an army o'er,
Or ship off senates to some distant shore;
A leaf, like Sibyll's, scatter to and fro
Our fates and fortunes, as the wind shall blow:
Pregnant with thousands flits the scrap unseen,
And silent sells a king, or buys a queen." Pope.

From the negociability thus conferred upon them, bills have been compared to bags of money; but it should be remembered that, in the former case, we transfer only *a right;* in the latter, the *property itself.* The comparison is best supported in those transferences which are made without recourse, since, in those instances, the bill passes from hand to hand without any alteration in the rights and duties of those interested in it, and without any one acquiring an additional security. In the simplest case, however, the rights arising on a bill may be preserved or lost by the conduct of the holder, and where there has been even one unqualified indorsation, the duties of the holder are of a delicate and important nature. But these will be more readily understood after we have pointed out the requisites of a bill.

Requisites of a Bill or Note.

The general requisites of a bill are, that it must be payable at all events; that it must be for payment of money only; and that the money must not be payable from any particular fund. Of the more special requisites the *first* is, that any bill or note drawn or made in Great Britain (though dated abroad *) or in its colonies, is, that it be written on paper *stamped* according to the law of the mother country or colony, as it happens to be drawn in the one or the other. The stamp-duty varies according to the sum in the bill, and the extension of the term of payment; but for these particulars, and the mode of complying with the provisions of the law, reference should be made to the statutes in force at the time. The present regulating statute is that of the 55th Geo. III. c. 184, both as to *inland* bills and notes, and bills of exchange drawn here *on* foreign countries. As to bills truly drawn in foreign states, not colonies of Great Britain, on traders in this country, our law takes no cognizance of them as to whether they are or are not stamped; but *promissory-notes* made *out* of Britain are declared *not* to be negociable or payable unless stamped agreeably to our laws. Bills drawn at home must also be written on the stamp appropriated for bills. If on a stamp of another denomination, though of equal or superior value, they are invalid if not got re-stamped, which they may be for payment of the duty and a penalty of 40s. when carried to the stamp-office before they are due, but when after due, the penalty is L.10. If written on a stamp below the proper value, a penalty is incurred of L.50, and the bills besides are *null* (Bell's *Com. on Bankrupt Law,* Vol. II. p. 249); but it has been found with us in England, that if a bill is *not* properly stamped, a neglect to present for acceptance or payment will not relieve parties who were *otherwise* liable in the *original debt* in respect of which the bill was granted. The relief, in this case, is granted by a court of equity, but which relief is not extended to remote indorsers, not responsible for the original debt. Relief, however, is given when a party has bound himself to grant a valid note or bill, but gives one by mistake or design on a defective stamp. Negociable bills under L.5 must, by 37th Geo. III. c. 32, be payable within twenty-one days, and bear the name of the *place* where they are made, without which also *checks* on bankers are liable to stamp-duty. Penalties are likewise imposed on the post-dating of such *checks,* or of bills for the purpose of reducing the duty by apparently shortening the term of payment; and there are provisions in those laws respecting bills drawn in sets or otherwise, with which every trader should make himself acquainted. This, however, it is very difficult to do in all its bearings; since the penalties and provisions of the prior statutes are retained in every subsequent one, except as therein specially altered. This is one great evil in our fiscal regulations. Where the law cannot be known, transactions are rendered uncertain, property insecure, and litigation is increased to a mischievous extent. But the worst evil is, that this state of the law increases in a prodigious degree the influence of the crown, by the power over traders which is thus placed in the hands of solicitors of stamps, excise, customs, and other crown officers.

---

* Chitty, 5th edit. p. 70, 7 T. R. 601. 4 Camp. *Law,* 269.

The other requisites of a bill are, *2dly,* That it should bear the name of the place at which it is made or drawn; and if the street and number of the house be added, it is easier to give and receive the notices that may be necessary in proper time. *3dly,* The *date* should be distinctly marked, and, if *written* at length, a higher protection would be afforded against accidental or intentional alterations and vitiations. If a bill have no date, the date of issuing will be held as the date of the bill. *4thly,* The time of payment should be clearly expressed; and a *time certain* is necessary to make the document *negociable;* that is to say, the payment must not depend on an event that can never happen, such as the *marriage of a person,* though it may on the *death. 5thly,* The *place* at which a bill is made payable should also, for the sake of safe negociation, be distinctly stated; because at that place *presentment* must be made both for acceptance and payment. If no place be mentioned, the place of doing business, if the acceptor have one, or, otherwise, his dwelling-house becomes the place of presentment. *6thly,* The sum payable should be clearly written in the body of the bill, and the superscription of the sum in figures will aid an omission in the body. This sum must in all cases be above 20s.; and if payable more than twenty-one days after date it must exceed L.5. *7thly,* It should contain an order or request to pay. *8thly,* Of bills drawn in parts or sets, each part or copy should mention the number of copies used, and be made payable on condition that none of the others has been paid. The *forgery* of an indorsement on one of the parts passes no interest even to a *bona fide* holder, and will not prevent the payee from recovering on the other part. *9thly,* Every bill should specify distinctly to *whom* the contents are to be paid; but a *bona fide* holder, or his executor, may fill up a blank, if one be left, for the name of the payee, and recover payment. (Chitty, 82; Bell, Vol. II. p. 251, &c.) *10thly,* If it be intended that a bill is to be negociable, it should contain the operative words of transfer "to order;" although, if the original intention be clear, these words may be inserted without a fresh stamp. (Chitty, 86.) *11thly,* It is advisable in all cases to insert *value received;* since, without these words, the holder of an *inland* bill for upwards of L.20 could not, in England, recover interest and damages against the drawer and indorser in default of acceptance or payment. Bills bearing for value received, and payable *after date,* seem also to possess advantages when lost, under the stat. 9th and 10th W. III. c. 17; but equity would probably extend these to indorsements; and 3d and 4th Anne, c. 9, it is thought, extends the same to notes. (Chitty, p. 196.) *12thly,* As to foreign bills, the drawee should attend to whether they are to be paid *with* or *without farther advice;* since the propriety of his accepting or paying will, in the one case, depend on his having received advice. The more carefully all these requisites are attended to, the greater is the security of all concerned against accidents and litigation. But traders, we fear, have too generally a prejudice in favour of that brevity which approaches to looseness of expression, and against that precision which alone can keep them out of difficulties.

General explanatory Rules and Usages.

Business hours.

Rules of giving Notices.

When a bill, check, or note, is payable *on demand,* or when *no time of payment is expressed,* it should be presented within a reasonable time after receipt, and is payable *on presentment,* without the allowance of any days of grace. It is yet *unsettled* (Chitty, 344, *et seq.*) whether bills drawn *at sight* are entitled to days of grace, though the weight of authority is rather in favour of them. If drawn at one or more days after sight, the days of grace must be allowed. The day on which a bill is dated is not reckoned one; but all bills having days of grace, become due, and must be presented and protested *on the third day,* and if that day be a Sunday or holiday, on the *second.* The rule for giving notice of non-acceptance or non-payment is different, since, if the day on which it should have been given be a day of rest, by the religion of the party, such as the Jews' Sabbath, the notices will be good if given on the next day. Calendar months are always understood with respect to bills; and if dated on the 29th, 30th, or 31st of January, payable *one month* after date, they will fall due on the *last day* of February, from which the days of grace are to be calculated. Presentments of bills should be made within business hours. These are generally considered to be in London from nine morning to six evening, but a protest has been held good against an ordinary trader when made at eight. This would not have been good in the case of bankers, whose hours (from nine to five in London) must be attended to. In Edinburgh, bankers' hours are from ten to three; traders' from ten to three, and from six to eight; but there are no Scotch decisions holding these as the only business hours. A verbal notice of the dishonour of an *inland* bill is good; but as such notice is always matter of parole evidence, it is better in every case to give notice in writing; and the regular mode of doing so is by post. Such notice, if put into the general post-office, or an authorised receiving-house, is good though it miscarry, provided the letter be regularly booked, and reasonable proof be made of its having been put into the post-office. If given only to a bellman in the street, it would not in such a case be good. When there is no post, the ordinary mode of conveyance, such as the *first* ship or carrier, is sufficient. As to *foreign bills,* notices of dishonour, with the respective protests, must be despatched by post on the day when the bills become due, or on which acceptance was refused, if any post or ordinary conveyance set out that day, and if not, by the next earliest conveyance. (Chitty, 291.) As to *inland* bills, notice should be made by the first post after the expiry of the day, when the parties reside at a distance; if in the same town, it is enough if the notice be made so as to be received within business hours of the following day; and this may be done by the twopenny or penny post, if receivable within the time mentioned. When a holder deposits his bill at his banker's, the number of persons entitled to notice is increased by one; and each party in succession is entitled to *twenty-four hours* for giving notice. (6 East 3. Bell, 263.) Such notice, as to inland bills, is necessary in England for preserving recourse as to the principal sum only. If protest be made, and notice given within fourteen days, the recourse is preserved as to *interest*, damages, and expences. In Scotland a protest is necessary in every case; and there is no distinction made as to the mode of recourse between principal and interest; but intimation to the drawer within *fourteen* days preserves recourse for the whole (Bell, Vol. II. p. 265); and it has been decided, that notice to an indorser may be good even after the fourteen days, if there has been no unnecessary delay, (*Fac. Col.* 2d June 1812.) But this applies only to *inland* bills, and a bill drawn from Scotland upon England is in Scotland held to be foreign. (Bell. Vol. II. p. 265.)

Effect of inevitable Accident.

Every bill should be presented for payment on the day upon which it falls due, unless that be rendered impossible by some unforeseen and *inevitable* accident, such as shipwreck, or sudden illness, or death. To preserve recourse, the accident, and the presentment of the bill as soon as possible afterwards, must be intimated without delay, and, if denied, proved by the party who seeks recourse. The same doctrine will hold as to presentments for non-acceptance, and notices of dishonour.

How to act when Bill lost.

But the loss or destruction of a bill is no excuse for not demanding payment and protesting; the protest in that case being made upon a copy or statement of the bill, if the party who has right to hold the bill has it in his power to make such a statement. If the destruction of the bill can be proved, action will be sustained in a court of law; if not, the redress is got upon giving an indemnity in a court of equity; but as equity will not interfere where law can, it is of importance in such a case, and indeed in all cases of difficulty, to resort at once to the best professional advice. Inconsiderate attempts to remedy neglects, or cure what is defective, generally make the case worse, and often implicate character.

Effect of Usury.

Cases of great hardship and difficulty frequently arose on bills granted partly for *usurious* consideration. A mighty benefit, however, has now been conferred by the statute 58th Geo. III. c. 93, which enacts, "That *no bill* of exchange or promissory-note that shall be drawn or made after the passing of this act shall, though it may have been given for a usurious consideration, or upon a usurious contract, *be void in the hands of an indorsee for valuable consideration*, unless such an indorsee had, at the time of discounting or paying such consideration for the same, *actual notice* that such bill, &c. had been originally given for a usurious consideration, or upon a usurious contract."

Effect of Gaming.

It is much to be regretted that the same protection was not extended by this statute to the *innocent holder* of a bill granted for a game debt. Such bills are still void in the hands of a *bona fide* indorsee. In Scotland it has been decided otherwise. (25th January 1740, Nielson; Bell, Vol. II. p. 210.) The rage for legislation has not yet extended itself to lawyers, who, as a body, can hardly be expected to display an anxiety to remedy defects which add to their emoluments and consequence. How much of the learning of this profession is wasted on niceties and difficulties that would readily yield to the spell of an act of Parliament! To the law, however, we owe this sound maxim, that, "unless it has been so expressly declared by the legislature, as it formerly was in the case of usury, and still is as to bills for *game* debts, illegality of consideration will be no defence in an action at the suit of a *bona fide* holder, without notice of the illegality, unless he obtained the bill after it became due." (Chitty, 105.)

Effect of Forgery.

Thus *forgery* does not vitiate a bill. The forged document is good to and against all parties, but those whose names are forged. Against one whose name is forged, it is true, it will neither support an action nor ground a claim; "yet if he have given credit to acceptances or indorsations as binding on him, forged by the same hand, he will be liable." (3 Esp. N. P. 60. 2 Bell, 250.) Subsequent approbation also does away an objection on the head of forgery or fraud, and generally all sorts of objections otherwise competent.

Effect of Vitiation

This doctrine holds as to vitiations when the stamp laws are not concerned; but without the consent of parties all vitiations or alterations of bills in material parts are fatal. (2 Bell, 252.)

Acceptance by Procuration

A clerk or servant may accept a bill for his master if authorised so to do; and authority will be inferred from a sanctioned practice. The law on this point is dangerous, and would require legislative revision. If the servant or agent do not explain the character in which he acts, but subscribes his own name simply, he will bind himself, not his employer.

Conditional Acceptance.

An acceptor may enlarge the term of payment, or accept for a part, or under any other condition not expressed in the bill; but in that case it is optional in the holder to take the acceptance as thus offered, or to proceed as if no such offer had been made; if rejected, the protest should bear the condition, and the rejection of it; it should also be kept in view, that a *holder* who accepts of a limited or conditional acceptance, liberates the drawer and prior indorser, unless he have their consent.

Indorsements.

Blank indorsements are held to be of the date of the bill until the contrary is proved. Indorsements after the term of payment, though for value, do not protect the indorsees like indorsements before maturity; very slight evidence is admitted as proof of knowledge of dishonour, and the holder in that case becomes liable to all exceptions which can be stated against the right of his immediate indorser, or the person who held the bill when it became due. When acceptance is refused, and the bill returned with protest, action may be raised immediately against the drawer, though the regular time of payment is not arrived. His debt, in such a case, is considered as contracted the moment the bill was drawn; if the date of the bill be prior to that of a commission of bankrupt, the debt, in such a case, may be claimed upon. As to current bills, and contingent claims, the case is unfortunately different; in these respects England might derive great help from the law of Scotland.

Duties of Drawee.

The *drawee*, who, having funds, refuses to accept, is responsible for the consequences to the *drawer*, and may also be sued for payment by the payee or holder, the presentment and protesting of the bill for non-acceptance, operating as an intimated assignment and complete transfer of the debt *to the holder*, who in Scotland is preferred to any subsequent arrester. The *drawee* who has no funds is not bound to accept; but, after protest for non-acceptance, he may accept supra-protest for the *honour* of the drawer and indorsers, or either of them. A *third party* may thus accept for *honour* supra-protest; and whoever does so, if he give immediate notice, and send off the protest, may have immediate recourse on the party or parties for whose honour he has interfered.

Payee or Holder.

It is the duty of a *payee*, when directed by the drawer, and of every one who is merely an agent for the owner, though acting gratuitously, to present a bill for acceptance. The time thought reasonable for this purpose is twenty-four hours, or at least within business hours of the day following that on which the bill was received. It is prudent in all holders of a bill to present for acceptance within this period; and *in all cases* where a presentment is made, and acceptance refused, notice should be given to all against whom it is meant to preserve recourse. A draught may be left twenty-four hours with the drawee, if no post go out in the meantime; but if he intimate within that time that he will not accept, or ask *more time* to consider, *notice should be given*. (Chitty, 288, 289.) A verbal acceptance, if it can be proved, or one by a separate writing, binds the drawee; but in Scotland none but a written acceptance on the bill will authorise the usual summary diligence. (Chitty, 217–270; 2 Bell, 69–240.) If the drawee had no funds, notice to the drawer is not necessary; but as the not having funds is a matter of fact to be proved, it is safer in this, and indeed in all other cases, to give the usual and regular notice. When a bill is drawn at some certain time *after sight*, presentment is *necessary* to fix the term of payment. Respecting bills of this description, both foreign and inland, the general rule is, that *due diligence must be used*. Foreign bills, so drawn, may be put into the circulation without acceptance as long as the convenience of the successive holders requires; and it has been found not to be *laches* (in Scotland *mora*, or undue delay) to keep a bill (at three days' sight) out in the circulation for twelve months; but if, instead of circulating, a holder were to lock it up, this would be *laches*. An unaccepted inland bill may also be put into circulation, and any holder, who does not circulate it, has a reasonable time, such as the fourth day respecting a bill drawn within twenty miles of London, for presenting it there for acceptance. Despatch and attention, however, are always advisable. It is said that when a bill has been already protested for non-acceptance, and due notice thereof given, it is not necessary to protest or to give notice on account of non-payment; but it is usual to do so, and the safer practice. The same rules, and the same time, should be observed as to non-payment, that are observed as to protest and notice, in the case of non-acceptance. When inland bills are made payable on a day named and fixed in the bills, it is common to delay presenting them for acceptance, until they can also be presented for payment, and then, if necessary, to protest for both; but it is better to make a presentment for acceptance as soon as it can be done in the ordinary course of business. It has already been stated, that notice either of non-acceptance when a presentment has been made, or for non-payment, *must* be given *to all the parties* to whom the *holder* intends to resort for payment.

Effect of Bankruptcy.

Bankruptcy is no excuse for neglecting any step in the negociation of a bill. If a party be bankrupt, notice of recourse should be given to him and his assignees; if *dead*, to his executor or administrator; if abroad, the notice should be left at his place of residence, if he have one, and a demand of acceptance or payment (when that is necessary) should be made of his wife or servant. Notice should also be made to one who merely guarantees payment; and a person who subscribes a bill not addressed to him, is held to be a collateral security. If notice be made to one indorser, he may give notice to prior indorsers, or to the drawer; and if done timeously, it will be available to the holder; but notice by a party, not party to the bill, nor agent for a party, will not be available.

Accommodation Paper.

Accommodation-bills are subject to the same rules as other paper, except among those who agree to lend their names or credit. Among them, the rule is, that he for whose use the money is to be raised, shall provide for the bill; but as all the others have an action of relief when forced to pay, they are entitled to notice. In Scotland this has been extended to the drawer when he is not the party for whom the credit was intended.

Cross-Paper.

With respect to cross-paper, it is held that mutual accommodations exchanged are good considerations for each other; that in case of bankruptcy, a dividend from any one estate is to be held as payment of all that can be demanded in respect of that debt; and that there can be no double ranking of the same debt. But questions often arise in such cases which require the utmost professional skill to comprehend and decide. In a short digest of this nature it is impossible to enter into the niceties of legal questions; and we can only observe generally, that parties should never act in cases of difficulty, without taking the best professional assistance.

The law respecting bills of exchange is less offensive to reason than almost any other branch of our law, since, where the law is silent here, recourse is had to the custom of merchants. Still there are many points which might easily be improved, if lawyers would set heartily about the work Lawyers, however, are seldom innovators, though the innovations required be only for the better; and very few others are able to legislate on matters of jurisprudence.

The best authorities respecting the law of bills are the treatises of *Chitty* and of *Bayley* as to English law, and Mr Bell's valuable *Commentaries on Mercantile Jurisprudence*, as to Scotch law.

(S. S.)

Tables.

TABLES RELATIVE TO THE EXCHANGE BETWEEN GREAT BRITAIN AND OTHER COUNTRIES.

ACCOUNT of the market prices of STANDARD GOLD AND SILVER BULLION, showing their relative proportions to each other;—the *real par* and course of exchange between London and Hamburgh, and the *per centage* in favour of and against London;—the *per centage* above and below the mint price of gold;—and the number of Bank of England notes in circulation from 1760 to 1819.*

		Price of Standard Gold *per* oz.			Price of Standard Silver *per* oz.			Their relative proportions to each other.		Par of Exchange with Hambro.		Course of exchange with Hambro.		*Per cent.* in favour of London.	*Per cent.* against London.	*Per centage* above the Mint price of Gold.			*Per centage* below the Mint price of Gold.			Bank of England Notes in Circulation.

* This table, with the exception of the column of Bank of England notes, from 1760 to 1809, is extracted from the second edition of Mr Mushet's pamphlet. The last ten years have been filled up from the accounts given in the *Reports on the Expediency of the Bank resuming Cash Payments*, laid before Parliament in 1819. The *fixed par* is taken at 34 schillings, 11 grotes, and ¼, which is esteemed the true *par* by the merchants, though it differs about ⅜ *per cent.* from the par (35s. 1d. Hamburgh currency), as estimated by Dr Kelly from the Mint regulations. The silver in the English pound sterling is valued throughout at 5s. 2d. an ounce. The bills on Hamburgh, from the negociation of which this table has been formed, have been invariably drawn at 2½ usances.

* Average of January and July.

§ Wherever a blank space is left, it shows that no prices of bullion are quoted of that date, either at Lloyd's or at the *Bullion Office* in the Bank of England.

‡ From 1797, the account of Bank of England notes in circulation is taken from the Table, in page 323 of the Appendix to the Lords' *Report on the Expediency of the Bank's resuming Cash payments.* On the 25th February 1797, the epoch of the *restriction* on cash payments, there were only L.8,640,250 notes in circulation.

† From 1800 to 1810, standard gold and silver in bars are not regularly quoted. Portugal gold in coin, being nearly of the same standard, has in several instances been quoted as standard gold. In those instances where standard silver is not quoted, the deficiency has been supplied by adding 2½d. to the ounce of new dollars, the computed difference in the value of the two standards.

Tables.

		Price of Standard Gold per oz.	Price of Standard Silver per oz.	Their relative proportions to each other.	Par of Exchange with Hambro	Course of exchange with Hambro	Per cent. in favour of London	Per cent. against London.	Per centage above the Mint price of Gold.	Per centage of Discount on Bank Notes.	Bank of England Notes in Circulation.

---

* It appeared from the evidence, taken before the Committee on Irish Exchange in 1804, that the expence of transmitting L.100 in cash from London to Dublin, and *vice versa*, varied from 1 to 1½ *per cent.*; and it is stated by Mr Foster (*Essay on Commercial Exchange*, p. 175), that in the long interval from 1728 to 1797, the exchange never varied beyond the expence of sending gold from the one country to the other, except in 1753, when the paper currency of Dublin had been very much depreciated. (See Mr Parnell's pamphlet *On the Principles of Currency and Exchange*, 4th edit. p. 168.)

Tables. III.—ACCOUNT of the Number of BANK OF IRELAND Notes in circulation, including Bank Post Bills, in each half year, commencing with the half year ending 1st January 1797 to 1st January 1819, inclusive. (From an Account printed by order of the House of Commons.) Tables.

IV.—PAR of EXCHANGE between England and the following places, viz. Amsterdam, Hamburgh, Paris, Madrid, Lisbon, Leghorn, Genoa, Naples, and Venice, the same being computed from the intrinsic Value of their principal Coins, by comparing Gold with Gold, and Silver with Silver, according to their Mint Regulations, and to Assays made at the London and Paris Mints. (Given in by Dr Kelly to the Committee of the House of Lords, appointed to inquire into the expediency of the Bank's resuming Cash Payments.)

FAROE, Faroer, or Feroe, a groupe of European islands, situated in the Northern Ocean, between Shetland and Iceland, about 200 miles north-west of the former. They appear to form the country described by the early Venetian navigators under the name of Friesland, though that term was afterwards applied by the English to the northern extremity of Greenland. These islands are twenty-two in number, of which the principal are Stremoe, Osteroe, Suderoe, Wangoe, and Sandoe. They are described at some length in the body of the work, under the head of Feroe; but since that time, a considerable mass of new information has been communicated by the work of the Rev. G. Landt, who resided there, as a clergyman, for upwards of twenty-five years; as well as by the voyage undertaken in 1812, with a laudable view to the promotion of mineralogical science, by Sir George Mackenzie and Mr Thomas Allan. We shall thus be enabled to introduce some additional particulars.

These islands consist throughout of rocks and hills, rising to a considerable height, and separated from each other by narrow vallies, or rather ravines. Although, however, these hills rise abruptly, there are often on their summits, or at different stages of their ascent, plains of considerable magnitude. They everywhere present to the sea perpendicular cliffs, broken into a thousand fantastic forms, and which, to those who sail along the coast, present at every turn the most picturesque and varied scenery. The highest peak is that of Skellingfell, in the island of Stromoe, which is supposed to rise about 3000 feet above the sea. The rocks consist generally of trap, and exhibit little variety of composition, though they present some striking geological phenomena. The zeolites and chalcedonies here collected have long supplied the best specimens of these minerals to the cabinets of Europe. Mr Allan was surprised to find those beautiful minerals so little prized in their native region, that no one in the capital could give him any idea where they were to be found. By his own search, however, he obtained some very splendid specimens, particularly of several rare species of zeolite.

The population of the Faroe Islands, according to a statistical table drawn up in 1812, amounted to 5209. Agriculture is in a very imperfect state, the infield, or cultivated land, being supposed to bear to the outfield, or uncultivated, the proportion of 1 to 60. The plough is scarcely ever used, being in fact ill suited to the rugged and uneven surface of which the islands consist. The ground is therefore turned up with the spade, care being taken not to destroy the roots of the grass. Horses and cows are few in number, and the latter give very little milk, in consequence, probably, of the coarse hay upon which they are fed. Sheep form the chief riches of the islanders, and the number possessed by them was calculated, in 1812, at 85,307. Some individuals have flocks of two or three hundred. These sheep are allowed to run about, both in summer and winter, without ever being housed, and in severe seasons suffer considerably. The wool is generally coarse, and is torn off the animals in so rough a manner, as often to lacerate the skin. The fishery, which was once considerable, has been neglected, and is now of little consequence. The catching of the numerous birds which build their nests upon the face of the cliffs, forms a great source of subsistence to the inhabitants. Those employed in this hazardous trade display great ingenuity, and the most adventurous spirit. Sometimes the fowler is let down from the top of the cliff by a rope fastened to his waist. At other times, where there is any footing at all, he climbs the steepest rocks, or, where that is impossible, has himself thrust up by poles made for the purpose. The puffin (Alca Arctica) is the most common of these birds, and the eider duck is here often shot for food.

The Danish government has given the monopoly of the trade of the Faroe Islands to a mercantile house at Copenhagen (Frische and Company), under the condition of supplying the inhabitants with a sufficient quantity of grain, at a constant fixed price. Should the market price be such as to render this a losing transaction, the merchant is indemnified by government. This care of provisioning the islands is probably superfluous; and the natural bad effects of a monopoly are felt in the high price of other imported articles,—a good jacket being often given for a few leaves of tobacco. The exports consist of hose knit on the islands, to the annual amount of 100,000 pairs, tallow, fish, train-oil, feathers, skins, and butter. During the late war between Britain and Denmark, the fort of Thorshaun was, in 1808, destroyed by Captain Baugh, lest it should afford harbour to privateers. A German adventurer, who assumed the name of Baron Hompesch, afterwards landed and plundered the place; but his conduct was handsomely disavowed by the British government, who even restored the value of the property of which the natives had been robbed. Finding, also, that the people, having lost their communication with Denmark, were in danger of suffering from famine, she permitted a limited intercourse to be carried on, under licence, from Leith. The peace has since restored all things to their usual channel.

Thorshaun, the principal place in the country, does not contain above 518 inhabitants. It is situated on the eastern coast of the island of Stromoe, upon a narrow tongue of land, having creeks on each side where ships may be safely moored. The houses are built of wood, and roofed with birch bark covered with turf; the greenness of which makes it impossible, at a very short distance, to distinguish the place from the surrounding fields. The character of the people is generally marked by great simplicity of manners, kindness, and hospitality.—See *A Description of the Feroe Islands*. By the Rev. G. Landt. Translated from the Danish. London, 1810.—*An Account of some Geological Facts observed in the Faroe Islands*. By Sir George Stewart Mackenzie, Bart. (*Transactions of the Royal Society of Edin.* Vol. VII.)—*An account of the Mineralogy of the Faroe Islands*. By Thomas Allan, Esq. (1812.) [illegible]

FERGUSON (Adam, LL. D.), a distinguished Philosopher and Historian, was born at Logierait, in the Highlands of Perthshire, on the 20th of June 1723. His father, the Reverend Adam Ferguson, a native of the neighbouring parish of Moulin, had been minister of Crathie and Braemar, in Aberdeenshire, from 1700 to 1714; and, on the eve of the ensuing Rebellion, had been translated to Logierait, where he passed the remainder of his long life, discharging the duties of his laborious charge with such exemplary piety, fidelity, and firmness, that, though at the period of his induction, the parishioners were almost universally hostile to presbyterian principles, he speedily secured the respect and admiration of all ranks; and, till the close of his incumbency, in 1754, retained a degree of influence which proved that his knowledge of mankind was not inferior to his zeal for their religious improvement. This excellent man left a numerous family, of whom Adam was his youngest son, by Mary Gordon, daughter of Mr. Gordon of Hallhead, in Aberdeenshire.

It is believed that Adam received the first part of his education at the village school of his native parish, under the superintendence of Mr John Conacher, of whose literary attainments little can now be ascertained, though some of his pupils are still alive. Whatever might be the merits of this teacher, they do not seem to have been estimated so highly as those of the schoolmaster of Dunkeld and Perth; to one or other of which places it was at this time customary for the parishioners of Logierait to send such of their sons as they wished to prepare for a course of academical study. Two, at least, of Mr Ferguson's younger sons attended the grammar-school of Perth, between the years 1732 and 1738, while Mr James Martin was Rector, and Mr Andrew Cornfute one of the assistants. Under the tuition of these able and diligent instructors, Adam is said to have made uncommon progress in classical literature; and, in addition to the benefit which he derived from his teachers, he possessed the advantage of living under the protection of a respectable citizen, William Ferguson, his relative, a merchant in the town, and at one time chief-magistrate.

Towards the end of autumn 1738, when he had entered into his sixteenth year, he was removed from school to the University of St. Andrews, where his father had commenced his studies fifty years before, under a very meritorious Regent, Mr John Row, son of the minister of Ceres; who, being grandson of the well-known David Ferguson, minister of Dunfermline, was induced, by the claims of kindred, as well as of duty, to pay particular attention to the improvement of a youth whom he soon discovered to be highly deserving of his favour. It is so happened, that one of the colleagues of Mr Row was still a master of St Leonard's College, and that all the other masters were of nearly the same standing with the elder Mr Ferguson, who was thus confirmed in his preference of the college in which he had prosecuted his own philosophical studies. At this very juncture, the Principal of St Leonard's College died, and the other Professors, at whose almost unanimous recommendation, Mr Tullideph was appointed to the vacant chair, anticipated the most prosperous results from his efforts to promote the good of an establishment which they considered as having fallen into disrepute, in consequence of the feeble and undignified administration of his predecessors.

The Greek class in St Leonard's College, was at this time taught with great reputation by Mr Francis Pringle, who had obtained his office in 1699; but, though no other teacher of that language in Scotland could pretend to rival him, the average number of students who were received annually under his charge, from 1738 to 1747, was not more than eleven; while the average of entries to the corresponding class in St Salvator's College scarcely amounted to six. Adam Ferguson was enrolled in Mr Pringle's class as a ternar, the same rank of students which, in the days of Buchanan, was characterized by the term *pauper*; that is to say, one who pays the lowest rate of fees. It has been alleged that Ferguson, after a comparative trial, was admitted one of the foundation bursars, having stood first in the list of successful competitors. If it were so, the victory was not very splendid, as, of the twelve who entered the class along with him, not more than eight (being of the denomination of ternars) could have been permitted to take a share of the contest.

Besides Pringle, the other masters in St Leonard's College were, John Craigie, admitted Professor of Philosophy in 1691, Ninian Young, Professor of Humanity, and Henry Rymer, Professor of Philosophy, both admitted in 1709; and David Young, Professor of Philosophy, admitted in 1716. Before the end of the Session 1739, Charles Gregory, Professor of Mathematics, resigned in favour of his son, David, who, though a very ordinary man, was the most popular teacher of geometry ever known in that University, which had many years before numbered among its Professors the inventor of the reflecting telescope.

The method of teaching in St Leonard's College at this period did not materially differ from that which had been pursued in the former century. The Professors, in general, followed the beaten track in which they had been guided by their predecessors; and the tasks which they exacted from the students were little more than exercises of memory. A young man of slender abilities might easily distinguish himself as much as his most ingenious associates, who might be apt to underrate acquirements which were more accessible to plodding industry than to original talents. We have good reason to believe that Ferguson acquired little more at this seminary than a high admiration of the Grecian and Roman literature, to the beauties of which he was more nearly introduced than he had hitherto been; and that his advances in the knowledge of philosophy were all made at a subsequent period. Even under the vigilant and severe inspection of Principal Tullideph, the discipline of the College was by no means good; and, in Mr Pringle's class particularly, some of the young gentlemen conducted themselves so improperly as to have narrowly escaped the disgrace of being refused their degrees, after they had undergone the usual trials. Mr Ferguson obtained the degree of Master of Arts on the 4th of May 1742, when he had nearly completed his nineteenth year. The Regent under whom he finished his course of physical study was Mr David Young, whose text-book was Keill's *Introductio ad veram Physicam*.

The minister of Logierait had attempted to induce some of his other sons to follow his own profession; but, as they had all testified a disinclination to this line of life, he determined to breed his youngest son to the church; and, accordingly, he was sent to the Divinity Hall at St Andrews, in November 1742, when the theological department of study was superintended by Principal Murison and Professors Shaw and Campbell; the last of whom, a man of talents and learning, was well known by his writings; but, like several of his predecessors in the same chair, he scarcely ever lectured at all. Mr Ferguson studied also a year or two at Edinburgh under Professors Gowdie and Cuming; but his attention appears to have been given chiefly to pursuits not immediately connected with his clerical views.

In the year 1745, when he had attended Divinity only one-half of the usual period, an appointment was offered to him, which he could not hold without ordination. It was represented to the General Assembly, that Lord John Murray, Colonel of the Highland Regiment (the 42d), was desirous of having a chaplain of the communion of the Church of Scotland possessed of the Irish language; and that Mr Adam Ferguson, though he had not studied divinity the full period of six years, was pitched upon for that office, provided the Assembly would allow the Presbytery of Dunkeld to take him on trials. The Assembly, in respect of the young man's capacity and good character, authorised the Presbytery to ordain him on passing his first trials; and, accordingly, he was ordained at Dunkeld, on the 2d of July 1745. A few days afterwards he joined the regiment, in which he continued to serve till 1757; about the beginning of which year he was elected keeper of the *Advocates' Library*, on the resignation of the celebrated David Hume. About a year after, Mr Ferguson was succeeded in this office by Mr William Wallace, *junior*, advocate.

In the course of the year 1767, Mr Ferguson rendered himself conspicuous by the interest which he took in the success of the Tragedy of *Douglas*, written by his friend Mr Home. He published a defence of the *morality of stage plays*, which, though its merit is not of the highest order, was admitted by the opposite party to be "the only piece on that side that was written with any tolerable degree of discretion." After Mr Home resigned his living in June 1757, Mr Ferguson and he retired to country lodgings at Braid, in the neighbourhood of Edinburgh, where they spent a few months in a course of laborious study, enlivened by the intercourse of friendship. As Mr Ferguson's campaigning habits had reconciled him to a migratory life, it is not easy to trace him through all his changes of residence. During his father's lifetime he had great satisfaction in making occasional excursions to the Highlands, and thinking aloud in his solitary walks, amidst the lakes and forests of Rannoch, or on the summit of his native mountains, where one of the most magnificent prospects in nature was displayed before his eyes. It was here that the lofty enthusiasm of his spirit was nursed and matured; and it was not so much in the intercourse with polished society, as in the wilds of Athol, that he acquired that dignity and ease of manner for which he was distinguished above most of the literary men of his country. To use his own expressive words: "If I had not been in the Highlands of Scotland, I might be of their mind who think the inhabitants of Paris and Versailles the only polite people in the world. It is truly wonderful to see persons of every sex and age, who never travelled beyond the nearest mountain, possess themselves perfectly, perform acts of kindness with an aspect of dignity, and a perfect discernment of what is proper to oblige. This is seldom to be seen in our cities or in our capital; but a person among the mountains, who thinks himself nobly born, considers courtesy as the test of his rank. He never saw a superior, and does not know what it is to be embarrassed. He has an ingenuous deference for those who have seen more of the world than himself; but never saw the neglect of others assumed as a mark of superiority."

In the year 1759, he was elected Professor of Natural Philosophy in the University of Edinburgh, in the room of Dr John Stewart. He had not made physical science the principal object of his inquiries; and, indeed, he had not studied it much more attentively than most young men do in the common routine of academical instruction. But with only four months to prepare for the labours of the winter, he qualified himself so well as to give universal satisfaction. He conducted this branch of education five years, and by adapting his lectures to the capacities of the young, contrived to render the study more interesting than it had been commonly considered. At this time he was a member of the well-known *Select Society* of Edinburgh, instituted in 1754, for the purpose of promoting philosophical discussion, and training the members to the practice of public speaking. The ardour of this society did not begin to languish till the year 1762, when another association, equally celebrated, was formed by the literary circle of Edinburgh; the design of which was to rouse the country to demand from the Legislature the establishment of a militia in Scotland. Mr Ferguson may almost be considered as the founder of this society; and it was at his suggestion that it received a name (The *Poker*) which was sufficiently significant in the ears of the initiated, but utterly unintelligible by strangers. His satirical pamphlet, entitled, *The History of Sister Peg*, was intended to forward the object of this patriotic society; and it is perhaps the only production connected with that cause, which, at this distance of time, is capable of exciting any interest.

In 1763, Mr Ferguson was applied to by the Earl of Warwick to take charge of his two younger sons, the Honourable Charles and Robert Greville, whose eldest brother Lord Greville had received part of his education under the eye of Principal Robertson. These young gentlemen resided some years in his house, and both they and their tutor Mr Macpherson repaid his attention to their improvement by the warmest affection and gratitude. Lord Warwick, who had been advised by General Clerk to place his sons under Mr Ferguson's care, was not insensible of the "great benefit they had reaped from his tuition, and advantageous as well as manly and friendly conversation." Mr, afterwards Sir John, Macpherson, at the same time acknowledged, that "to him he owed all his knowledge, as well as all his success in life."

On the appointment of Mr Balfour to the Professorship of the Law of Nature and Nations, in 1764, Mr Ferguson was elected by the Magistrates of Edinburgh to succeed him in the chair of Moral Philosophy. This had long been a favourite object of his ambition, and about ten years before, when the able and accomplished Mr Cleghorn was on his death-bed, he urged his young friend to apply for the office, which, in his apprehension, no man was more capable of adorning. Mr Cleghorn, after expressing his regret at having no such influence with the patrons as to secure such an arrangement, added, as Mr Ferguson sometimes related with much emotion, "I can only say of you, as Hamlet did of Fontinbras, *He has my dying voice.*"

Mr Ferguson entered on his new duties with a degree of spirit and activity, from which the most splendid results were to be anticipated. In one particular, his mode of lecturing was singular, and not easily imitated. After having delineated the general plan of his course, and committed it to writing, he resolved not to write a system of lectures, but to endeavour to make himself master of every part of his subject, and to trust to the moment of delivery for the expression of his sentiments. This method of discoursing was in his hands very happily executed; but its success depended, in a great measure, on the state of his health and spirits, as well as upon the interest excited by the different subjects of discussion. Perhaps no lecturer, with the exception of his immediate successor, was ever more admired. His class was crowded by great numbers of gentlemen of high rank and official station, as well as by younger students. In the mean time, eagerly as he applied to the discharge of his professional duties, his attention was extended to other branches of inquiry; and within little more than a year after he commenced his labours as a lecturer on morals, he sent to the press, his *Essay on the History of Civil Society*; a work which was received with an expression of public applause, which even exceeded the high expectations of his friends. "Ferguson's book (says Mr Hume, writing to Dr Robertson from London) goes on here with great success." Gray, the poet, says, "There are uncommon strains of eloquence in it; and I was surprised to find not one single idiom of his country (I think) in the whole work." Mr Hume, in a letter to the author (dated 10th March 1767), congratulates him on the success of the book, adding that he had "met with nobody that had read it who did not praise it. Lord Mansfield is very loud to that purpose in his Sunday Societies. I heard Lord Chesterfield and Lord Lyttleton express the same sentiment; and what is above all, Caddel, I am told, is already projecting a second edition of the same quarto size." Mr Hume then informs him, that Lord Shelburne and Lord Bute were among his most zealous partizans; the last declaring the book one of the best he ever read. Charles Townshend appears to have been of the same opinion, as he read it five times over.

General Clerk had pressed the author to dedicate his work to Lord Shelburne, who had signified his intention of offering Mr Ferguson the government of West Florida; upon which occasion his Lordship laughed very heartily, when the General expressed his conviction, that Mr Ferguson was more usefully employed as a teacher of science. The book, however, appeared without any dedication. In the course of the following year, Lord Shelburne intimated a hope of getting Mr Ferguson established with a proper appointment at Oxford; and some other persons of influence meditated a design of employing him in one of the departments of state. This purpose was frustrated in all probability by a temper, which did not permit him to accommodate himself to the views of those whose maxims of conduct he did not entirely approve. Another circumstance may be considered as having also operated to obstruct the fulfilment of the schemes which were devised for his advancement. At this time he married Miss Burnet, a young lady nearly connected with his mother's family, and still more nearly related to his intimate friend Dr Black. Soon afterwards he began to cultivate a farm in the parish of Currie, and, at a considerable sacrifice of private interest, gratified his taste for improvement by transforming a barren heath into a scene which became distinguished for beauty and fertility.

It was impossible, however, for any combination of circumstances to abate his literary activity; and he not only continued to conduct the business of his class with unremitted diligence, but seized every interval of leisure which he could command, to collect materials for a history of the Roman Commonwealth. While he was proceeding in his researches, he was solicited by Philip, Earl of Stanhope (the editor of Dr Robert Simson's posthumous works), and the other guardians of Charles, Earl of Chesterfield, to superintend the education of that young nobleman, then in his nineteenth year. The negociation was conducted through the mediation of Dr Adam Smith, who, judging the offer to be advantageous to his friend, exerted himself with great earnestness to induce him to accept it. Lord Stanhope was extremely anxious to obtain the able services of Dr Ferguson without delay, as he conceived it to be of the utmost consequence to his young kinsman to be placed under the care of "a person so well qualified to complete the remaining part of his education, and to repair the neglects, omissions, and errors, which had unfortunately been committed in the former part of it." The proposal had originally been made early in the year 1773, and was renewed in December, soon after the commencement of the session of the college, when Dr Ferguson was engaged not only in teaching his own class, but also in lecturing on natural philosophy, the professorship of which had recently become vacant by the death of his relation Mr Russell. He was not able to prevail on the patrons to accept of a substitute to complete the labours of that session; but after obtaining leave of absence for the next session, he joined his young charge at Geneva, in May 1774, and at first entertained hopes that his labours might prove beneficial. The connection, however, was not so agreeable as he expected, and it terminated about twelve months afterwards. In the mean time, he had very nearly been deprived of his office in the University. The town-council had, at his desire, appointed Mr John Bruce (then assistant, and afterwards successor to Mr Stevenson) to teach the Moral Philosophy during the session 1774 and 1775; but before the conclusion of the session, they thought fit to rescind this act, and to declare the office vacant. His friends in the University, particularly Drs Robertson, Blair, and Black, were exceedingly indignant at this proceeding; more especially as Sir John Pringle had been permitted to be several years absent; and at that very time the Professors of Mathematics, and of the Theory of Medicine, had both been allowed to discharge their duty by substitutes for two years without quarrel. As the council, however, seemed to have determined to fill up the place by a new election, it became necessary for his friends to apply to the Court of Session to put a stop to their proceedings. "I have been much obliged (says he, in a letter to a friend) to the general voice that was raised in my favour, as well as to the ardent zeal of particular friends. Ilay Campbell (afterwards Lord President) has given me proofs of friendship which I can never forget. Pulteney has behaved to me in every thing as he would have done at the beginning of the *Poker Club*. I have always been an advocate for mankind, and am a more determined one than ever; the fools and knaves are no more than necessary to give others something to do."

After his return, he continued, as formerly, to divide his time between his literary and agricultural pursuits, and engaged occasionally in the political controversies which agitated the country during the progress of the American war. Besides his pamphlet, in answer to Dr Price's observations on liberty, he communicated his views from time to time to Sir William Pulteney, and other members of Parliament; and when it was resolved by government to send out Commissioners to quiet the disorders in the colonies, he was appointed secretary to the Commission. It appears from a letter of General Putnam, dated July 1778, that the nomination of Dr Ferguson was very agreeable to the more intelligent part of the Americans, who, not without reason, were dissatisfied to find that the commissioners were fettered by restrictions, which rendered their appointment nugatory. "I am very sorry (he writes) that the Parliament of Great Britain is still so blind to their own and our interest, as to send Dr Ferguson and the rest of the worthy gentlemen over to America with limited power, and that to last only till July 1779, and then to be revoked by them if they think fit, by which means I am deprived of seeing your friend Dr Ferguson, which gives me great pain, as I always have heard of his being a gentleman of the first character for learning, good sense, and humanity." It is well known, that the Commissioners returned without accomplishing the object of their mission; but they had an opportunity of acquiring more useful information of the state and temper of the country than government had received in all the previous course of the contest. While Dr Ferguson was absent during the session 1778, 1779, his place was supplied by Mr Dugald Stewart, who, about five years afterwards, was destined to succeed him in the Chair of Moral Philosophy.

In the year 1780 he was seized with an attack of apoplexy, which, though not violent, was sufficient to alarm his friends for his safety. This formidable affection did not, in the slightest degree, impair the force of his understanding; and so abstemious did he afterwards become, as not only to secure himself against the recurrence of the disease, but to enjoy almost uninterrupted health for more than thirty years. As he could not now venture to lecture as formerly without the use of written notes, he therefore found it necessary to write out a course of instruction to be read during the remainder of his incumbency. In his endeavours to recover the substance of his lectures, he availed himself of the notes taken by intelligent young men, who had studied under him different sessions, and who thus might be expected to have preserved the various modes in which he had stated his doctrines, and the different arguments and illustrations by which he had happened to supply in one session what might have been omitted in another. But in the prospect of soon relinquishing his office, it was scarcely conceivable, that the compilation which he thus executed could possess all the excellencies which he was capable of imparting to it; more especially as he was now busy in carrying his great historical work through the press. This was the *History of the Progress and Termination of the Roman Republic*, in three volumes quarto, published in 1783; a book which not only delights by the clearness of its narrative, and the boldness of its descriptions, but instructs and animates by profound and masterly delineations of character, as well as by the philosophical precision with which it traces the connection of events. It is written in that tone of high-minded enthusiasm, which, if it can only snatch from oblivion whatever is noble and generous in the record of human actions, regards the graces of style as objects merely of secondary account, and is chiefly studious of impressing the lessons of wisdom, which may be gathered from the survey of distant ages.

The fatigues and anxieties of public teaching now became oppressive to his spirits, and not altogether favourable to his health; and he therefore deemed it expedient to resign his office in 1784, when he had completed his sixty-first year. Mr Dugald Stewart, then Professor of Mathematics, succeeded to his office; and in order to entitle Dr Ferguson to retain his salary, he was conjoined in the Professorship of Mathematics with the late lamented Mr Playfair. He now proceeded to revise the notes of his lectures on ethics and politics, with a view to publication; and, in 1792, the work appeared under the title of *Principles of Moral and Political Science*. Though composed under disadvantageous circumstances, and though it has omitted many of the questions which were treated in his elementary course, it contains an admirable view of the systems both of ancient and modern philosophers, particularly on the foundations of moral approbation, and the sources of private happiness and public security. The authors to whose suggestions he was most indebted were Xenophon, Plato, and Aristotle, among the Greeks, Cicero and Seneca among the Latins, Epictetus and Antoninus among the later scholars of the Grecian school; and, among the moderns, Shaftesbury, Hutcheson, Montesquieu, and Adam Smith. It has been considered as a blameable omission in this work, that too slight notice is taken of the importance of religious principle; and the author seems to have been aware that he had exposed himself to this objection. No man, however, was ever more anxious to establish the foundations of natural theology, and to strengthen the arguments for a future state; on which subjects the work abounds in passages of uncommon beauty.

After the publication of this work, Dr Ferguson, now in his 70th year, resolved to pay a visit to the ancient metropolis of the world. He passed a short time at some of the principal cities of Europe, Berlin, Vienna, Florence, Naples, and Venice, and resided part of the winter 1793 at Rome, in all of

Ferguson.

which places his reception was extremely flattering. He was elected a member of the Academy of Berlin, as well as of other learned societies. Upon his return to Britain in 1794, he took up his residence at Nidpath Castle in Tweeddale, whence he soon removed to Hallyards in Manor Water. In this agreeable retreat he spent the next fourteen years of his life, a longer period than he had ever before resided in any one place. At last, however, when his sight and his hearing had in a great measure failed, he deemed it advisable to settle in a town, where he might occasionally enjoy the conversation of intelligent friends; and his early prepossessions induced him to settle at St. Andrew's. Here his strength gradually declined, but the vigour of his mind continued unimpaired as long as he lived. No man took a more lively interest in the great events which were then passing in the world, or contemplated more anxiously the consequences of the arduous struggle which his country sustained. He lived long enough to witness the triumphant issue of the contest, and, after a short illness, he died on the 22d of February 1816, in the 93d year of his age, leaving three sons and three daughters.

In the various situations which it was his lot to occupy, he had uniformly conducted himself with a dignity and decision which bespoke the elevation and force of his mind. As a military chaplain, he happily united the strict decorum of the clerical character with the unembarrassed address of a man of the world; so that he, at the same time, secured the respect of the officers, and the devoted attachment of the private soldiers. It was while accompanying the army on different expeditions, one of the first of which was an ill-conducted descent on the coast of Bretagne in 1745, that he applied his mind to the study of the art of war; and it cannot be denied that he excels particularly in the description of martial evolutions. In private life his conversation was easy and elegant, and among his intimate friends enlivened by a fascinating gaiety and refinement of humour. He was not very patient of contradiction, and rather apt to testify his contempt of assumed superiority.

His writings are,

1. *A Sermon,* preached in the Erse language to his Majesty's First Highland Regiment of Foot, commanded by Lord John Murray, at their cantonment at Camberwell, on the 18th day of December 1745. By the Rev. Mr A. F., chaplain to the said regiment, and translated by him into English, for the use of a lady of quality in Scotland, at whose desire it is now published. Lond. 1746.

2. *The Morality of Stage Plays seriously considered.* Edin. 1757.

3. *A Pamphlet on the Militia.* Lond. 1758.

4. *The History of the Proceedings in the Case of Margaret, commonly called Sister Peg.* Three editions. Lond. 1762. Another 1777.

5. *Analysis of Lectures on Mechanics.* Edin.

6. *An Essay on the History of Civil Society.* Lond. 1767. This book has passed through many editions, and has been translated into almost all the European languages. A translation into German was published at Leipsig in 1768, under the title of ***Bersuch über die Geschichte der Burgerlichen Gesellschaft.*** A French translation, by M. Bergier, was published in 1783.

Ferguson || Fermanagh.

7. *Analysis of Pneumatics and Moral Philosophy,* A German translation, by Mr Garve of Leipsig, is said to have been well executed. Edin. 1766. 55 pages 12mo.

8. *Institutes of Moral Philosophy,* 1769. 319 pages 12mo.—Another edition, revised and corrected 1773. 294 pages. A translation of this edition into French was published at Geneva in 1775, and it had the advantage of being revised by the author.—A third edition, enlarged, was published at Edinburgh 1785. 317 pages 12mo. This elementary work has been used as a text-book in several foreign universities. A translation into the Russian language (from the German) was printed at Moscow in 1804.

9. Remarks on a pamphlet lately published by Dr Price, entitled, *Observations on the Nature of Civil Liberty, &c.* in a letter from a gentleman in the country to a member of Parliament. Lond. 1776. These remarks having been addressed to Sir Grey Cooper, Secretary of the Treasury, were printed by his direction.

10. *The History of the Progress and Termination of the Roman Republic.* 3 vols. 4to. Lond. 1783. A translation into German was printed at Leipsig in 1784. It has been translated into several other modern languages, and has passed through a number of English editions, one of which was printed at Basle in Switzerland, in 1791.

11. *Principles of Moral and Political Science,* being chiefly a retrospect of lectures delivered in the College of Edinburgh. 2 vols. 4to. Lond. 1792.

12. *Minutes of the Life and Character of Joseph Black, M. D.* 1801. (Published in the *Transactions of the Royal Society of Edinburgh.*)

13. *Biographical Sketch, or Memoir of Lieutenant-Colonel Patrick Ferguson.* Edin. 1817. (This tract, though printed, has not been published for sale.)

He has left behind him many interesting papers on the subjects which had chiefly occupied his thoughts from the time of his last academical appointment, but a great mass of letters, and other valuable documents, had been indiscriminately destroyed by his direction, some years before his death. (c. c. c.)

Situation and Extent.

FERMANAGH, a county in Ireland, situated in the province of Ulster, having the counties of Donegal and Tyrone on the north, Tyrone and Monaghan on the east, and Cavan and Leitrim on the south and west. Its extent is about 694 square miles, or nearly 450,000 English acres, of which a considerable proportion is covered by water, and much of the rest of the surface is rugged and mountainous, particularly on the west, where it is bounded by Leitrim. But it is in general better wooded than other parts of Ireland. The ash grows in the hedge rows; beeches come to a large size, and also the yew, near Lough Erne; and fir oak, and yew are found in the bogs.

Scenery. Lough Erne.

The grand feature in the natural scenery of this county is Lough Erne, which occupies about one-eighth of the surface, and stretches through its whole length, forming two large lakes, connected by a channel, like a river, six miles long. The upper lake is nine miles in length, and, at a medium, about three broad, and the lower, which is ten miles long, varies in width from two to eight miles. It discharges itself at the north-west by a rapid current of about seven miles, forming a grand cataract, where the water is precipitated into the sea at Ballyshannon, besides a beautiful fall at Beeleck, a little higher up. This noble piece of water is for the most part closely surrounded by high grounds that run their woody promontories into the lough, and retire from it in every direction, and contains more than three hundred islands, in some instances half a mile apart. They are of various sizes, some of them having an area of several square miles. A few are adorned with gentlemen's seats and pleasure-grounds, and most of them well-wooded, the whole presenting a great variety of delightful scenery.

Monastic Ruins. On one of these islands, called Devnish, are the ruins of several ancient buildings; a church dedicated to St Molush, and near it the saint's house, entirely roofed, and finished with cut stone, and his bed, a stone trough, which is still held in great veneration; and an abbey at a little distance, having a belfry arch of black marble, with a stair of 83 steps, near which is St Nicholas's well, to which many yet resort for relief. There is also a beautiful round tower, in a high state of preservation, 82 feet high, and 49 in circumference, said to have been built about the middle of the sixth century.

Lough Erne contains most of the fish that are found in other fresh water lakes, and is noted for its salmon and eels, particularly the latter. Four of the eel weirs near the falls of Beeleck afford a rent of L.100 each. There are several other lakes in the county, and a few streams that fall into Lough Erne, but none of them considerable.

Estates. Estates, in this county, are large. Three proprietors, mentioned by Wakefield, have L.13,000 a year each, and other three from L.6000 to L.7000. According to the same writer, the rent, taken at twenty-five shillings the green acre, must be equal to about 14s. the English acre; but what proportion this description of land bears to the whole does not appear. The leases are now most commonly for 21 years and a life.

Farms In the northern part of the county, the farms are larger and more productive than in most other parts of Ulster. Oats, barley, potatoes, and flax, are the principal crops; very little wheat, clover, or turnips being cultivated, except in small patches near the towns. The high grounds are chiefly occupied in rearing cattle, and much of the better pastures with dairy stock. There are no large flocks of sheep, and their breed of this animal is of a very inferior description.

Labourers. The price of common labour in 1809 was 1s. a day; but labourers for hire being scarce in those parts where the farms are small, 1s. 6d. and 2s. was sometimes paid. "The poor," says Wakefield, "eat wheaten bread and drink tea;" yet he elsewhere observes, that "the inhabitants are poor, and their cabins are wretched huts, with a wattled door, lined with a straw mat in the inside." Turf is the only fuel.

Manufactures. Linen 7-8ths wide is manufactured to some extent, and there are several bleachfields which finish for sale the linens sent to England. Illicit distillation is said to be very general, much of the oats and barley grown in the county being consumed in this way.

Fermanagh is in the ecclesiastical province of Armagh, and is divided into eighteen parishes, of which fifteen belong to the diocese of Clogher, and three to that of Kilmore. It is computed that the Catholics exceed the Protestants in number in the proportion of three to one. None of the former have property enough to entitle them to be on the grand jury.

Representation. The other subdivisions are baronies, of which there are five to the east of Lough Erne, and three on the west. Two members are sent to Parliament from the county, and one from the borough of Enniskillen, the only town in it of any extent. The number of freeholders, a few years ago, according to Mr Wakefield, was 5000; but the three greatest proprietors, when unanimous, can always return what members they please. One of them, the Earl of Enniskillen, is also patron of the borough, which has twelve self-elected burgesses.

There is little or no gradation of rank here; the only intermediate classes between the few great proprietors and the labourers, being the small squire and the large farmer, neither of them a numerous body. A military turn has long prevailed among the inhabitants. The protestants are a fine race of people, much superior in appearance to those of any of the northern districts.

In 1790, Fermanagh was computed to contain 11,969 houses, and 71,800 inhabitants; but by the last census, the population is found to be 111,250, or at the rate of one person for about four acres.—See Young's *Tour in Ireland*.—Beaufort's *Memoir of a Map of Ireland*.—Newenham's *View of the Natural, Political, and Commercial Circumstances of Ireland*.—Wakefield's *Account of Ireland, Statistical and Political*; and the *Parochial Survey of Ireland*, Vols. I. and II. (A.)

FERMAT (PETER DE), equally celebrated as a restorer of ancient mathematics, and an original author of modern improvements, was born in 1590.

His public life was occupied by the active duties attached to the situation of a Counsellor of the Parliament of Toulouse, in which he was distinguished both for legal knowledge, and for strict integrity of conduct. Besides the sciences, which were the principal object of his private studies, he was an accomplished scholar, an excellent linguist, and even a respectable poet.

His *Opera Mathematica* were published at Toulouse, in two volumes folio, 1670, and 1679; they are now become very scarce. The first contains the *Arithmetic of Diophantus*, illustrated by a commentary, and enlarged by a multitude of additional propositions. In the second we find a *Method or the Quadrature of Parabolas* of all kinds, and a *Treatise on Maxima and Minima, on Tangents, and on Centres of Gravity*; containing the same solutions of a variety of problems as were afterwards incorporated into the more extensive method of fluxions, by Newton and Leibnitz; and securing to their author, in common with Cavalleri, Roberval, Descartes, Wallis, Barrow, and Sluse, an ample share of the glory of having immediately prepared the way for the gigantic steps of those illustrious philosophers. The same volume contains also several other treatises on *Geometric Loci*, or *Spherical Tangencies*, and on the *Rectification of Curves*, besides a restoration of *Apollonius's Plane Loci*; together with the author's correspondence, addressed to *Descartes, Pascal, Roberval, Huygens*, and others.

It was too much Fermat's custom to leave his most important propositions wholly undemonstrated; sometimes, perhaps, because he may have obtained them rather by induction than by a connected train of reasoning; and, in other cases, for the purpose of proposing them as a trial of strength to his contemporaries. The deficiency, however, has in many instances been supplied by the elaborate investigations of Euler and Lagrange, who have thought it no degradation to their refined talents, to go back a century in search of these elegant intricacies, which appeared to require further illustration. It happened not uncommonly, that the want of a more explicit statement of the grounds of his discoveries deprived Fermat, in the opinion of his rivals, of the credit justly due to him for accuracy and originality. It was thus that Descartes attempted to correct his method of maxima and minima, and could never be persuaded that Fermat's first propositions on the subject were unexceptionable. Fermat was however enabled to pursue his favourite studies with less interruption than Descartes; and the products of his labour were proportionate, as Lacroix remarks, to the opportunities that he enjoyed, as well as to the talents that he possessed.

There is a very ingenious proposition of Fermat, which deserves to be particularly noticed, on account of the discussion that it has lately excited among mathematical philosophers. He has demonstrated that the true law of the refraction of light may be deduced from the principle, that it describes that path, by which it can arrive in the shortest possible time from any one point of its tract to another; on the supposition, however, that the velocity of light is inversely proportional to the refractive density of the medium; and the same phenomena of refraction have been shown, by Maupertuis, to be deducible, upon the opposite supposition with respect to the velocities, from the law of the minimum of action, considering the action as the product of the space described into the velocity. But the law of Fermat is actually a step in the process of nature, according to the conditions of the system to which it belongs in its original form; while that of Maupertuis is at most only an interesting commentary on the operation of an accelerating force. It was Newton that showed the necessary connection between the action of such a force and the actual law of refraction; demonstrating that all the phenomena might be derived from the effect of a constant attraction, perpendicular to the surface of the medium; and except in conjunction with such a force, the law of Maupertuis would even lead to a false result. For if we supposed a medium acting on a ray of light with two variable forces, one perpendicular to the surface, and the other parallel to it, we might easily combine them in such a manner as to obtain a constant velocity within the medium, but the refraction would be very different from that which is observed, though the law of Maupertuis would indicate no difference: so that the law must be here applied with the tacit condition, that the refractive force is perpendicular to the surface. In M. Laplace's theory of extraordinary refraction, on the contrary, the tacit condition is, that the force must *not* be perpendicular to the surface: so that this theory not only requires the gratuitous assumption of a different velocity for every different obliquity, which is made an express postulate, but also the implicit admission of the existence of a force, determinate in direction and in magnitude, by which that velocity is modified, and without which the law of Maupertuis would cease to be applicable. It may indeed be said, that the supposition of a medium exhibiting unequal velocities, and attracting the light perpendicularly, is unnatural; and that the law is the more valuable for not being applicable to it: but a mathematical equation is true even with respect to impossible quantities; and a physical law, however useful it may be, requires physical proof; and it will not be asserted that the law of Maupertuis has been or can be established, by physical evidence sufficiently extensive to render it universal.

Our author died in 1664, or the beginning of 1665, at the advanced age of 74. He left a son, Samuel de Fermat, who was a man of some learning, and published translations of several Greek authors.

((S. F.))

FICHTE (JOHN THEOPHILUS), a late eminent German metaphysician, was born at Rammenau, a village of Lusatia, on the 19th of May 1762. His father was a ribbon manufacturer, and carried on a small trade in haberdashery. A wealthy person in the neighbourhood, having been struck with the extraordinary genius which young Fichte displayed, put him to school, in order to give him an opportunity of cultivating his talents; but the boy becoming impatient of restraint, ran off, and was found sitting on the banks of the Saale, with a map, on which he was endeavouring to trace the way to America. From this period he seems to have prosecuted his studies in an extremely desultory manner; occasionally attending the lectures of the professors of Wittemberg and Leipsic, without devoting his attention exclusively to any particular science. Theology, however, appears to have been his favourite study; and this predilection is conspicuous in many of his subsequent writings, which are distinguished by a singular mixture of philosophical and religious mysticism. When he left the university, his situation was by no means enviable. He possessed no fortune to enable him to indulge in the luxury of philosophical speculation; and, in spite of his decided aversion to every kind of constraint, he was compelled, by the necessity of his circumstances, to accept of the situation of tutor in the family of a Prussian gentleman. His residence in that country enabled him to cultivate the acquaintance of the celebrated philosopher of Koningsberg, to whose judgment he submitted his first work, the *Critical Review of all Revelations*, which was published, anonymously, in 1792. In the literary journals, this production, which had attracted considerable attention, was ascribed to the pen of Kant, until the real author made himself known.

Having received fifty ducats from a Polish nobleman, in whose family he had been tutor, Fichte set out on a course of travels through Germany and Switzerland, and afterwards married a niece of Klopstock's at Zurich. In 1793, he published the first part of his *Contributions towards rectifying the Opinions of the Public respecting the French Revolution.* This book, which is written with considerable force and originality, created a great sensation in Germany, and was violently attacked in consequence of a new and apparently dangerous theory which the author advanced relative to the social contract. The book, however, was perused with great avidity, but the attacks to which we have alluded probably prevented him from publishing the continuation.

The reputation of Fichte was now so well established, that he was soon after appointed to the philosophical chair at Jena, as successor to Reinhold, who had been called to the University of Kiel. Here he commenced his lectures by a programme, in which he endeavoured to give an idea of the *Doctrine of Science* (*Wissenschafts-lehre*), the name by which he distinguished the principles of that system of transcendental idealism, which he afterwards more fully developed. Besides the ordinary duties of his professorship, he gave a regular course of lectures, in the form of sermons, every Sunday, in the year 1795, *on the Literary Calling*, which were numerously attended. Having established the principles of his doctrine of science, he endeavoured to extend their application to the several departments of philo[illegible] and, with this view, he published, in 1796, his *Fundamental Principles of the Law of Nature;* and two years afterwards, his *System of Morals.* In conjunction with Niethammer, he also published a philosophical journal, in which some articles were inserted, containing certain philosophical views of religion, which were considered by many as tending directly to atheism. Among other objectionable propositions, it was maintained that God was nothing else than the moral order of the universe; and that, to worship God as a being who could only be represented as existing in time and space, would be a species of idolatry. One of Fichte's colleagues called the attention of the Saxon minister Burgsdorf to these heretical propositions; and the consequence was, the rigorous confiscation of the work throughout the whole of Saxony. Fichte and his friend Forberg wrote an *Appeal to the Public,* and several *Apologies,* in order to exculpate themselves from the imputation of atheism. The government of Weimar behaved, on this occasion, with prudence and moderation; but the celebrated Herder, Vice-President of the Consistory, took part against Fichte. Eberhard on the other hand, although hostile to the metaphysical system of Fichte, undertook his defence. The controversy was carried on with great violence, and excited considerable ferment throughout the whole of Germany.

In the mean time, Fichte resigned his professorship at Jena, and repaired to Berlin, where he experienced a very flattering reception. Here his time was occupied in giving private lectures, and in composing his various writings. In 1800, he published a short treatise, entitled, *The Exclusive Commercial State,* containing one of those philosophical systems of political economy from which the praise of ingenuity cannot be withheld; while, at the same time, the most cursory view of the general principles on which it is founded must be sufficient to convince us that it could never be advantageously reduced to practice.

About this period, Fichte met with a formidable rival in Schelling, who had formerly been a warm partizan of the *doctrine of science,* but who now separated from his master, and propounded a new metaphysical theory of his own, which soon acquired a large share of popularity at the German universities, especially at Jena. Fichte, indeed, endeavoured to modify his theory of the *doctrine of science,* and to present it to the world in a new and more attractive form; but he never again recovered the sway he had formerly held over the public mind. Meanwhile, his ardent wish to be again placed in an academical chair was at length gratified by M. de Hardenberg, who, in 1805, procured for him the appointment of ordinary professor of philosophy in the university of Erlangen. This appointment was accompanied with the especial favour of being permitted to pass the winter at Berlin, in order to continue his lectures there. This state of amphibious professorship, as his friends used to call it in jest, did not last long. During the summer of 1805, he delivered at Erlangen his celebrated lectures, *on the Essence of the Literary Character* (*über das Wesen des Gelehrten*). The following winter, he delivered to a numerous audience the course which he afterwards published under the title of *Guide to a Happy Life.* This was one of those publications in which he attempted to present his metaphysical doctrines to the public in all their sublimity, and, at the same time, with such clearness, as would make them intelligible to common readers.

The disasters which assailed the Prussian monarchy, in 1806, were attended with serious consequences to Fichte. Erlangen having ceased to be a Prussian university, he did not await the entry of the French into Berlin, but fled to Koningsberg, and from thence to Riga. In the summer of 1807, he delivered a course of philosophical lectures at Koningsberg. The peace which ensued enabled him to return to Berlin, where he pronounced his famous *Orations to the German Nation,* which were enthusiastically read and applauded throughout all Germany. When the University of Berlin was founded, he obtained, through the interest of M. de Humboldt, the situation of rector, which secured to him an honourable revenue, while his rank, as first professor of philosophy, gave him great academical influence. His health, however, had suffered considerably from the shocks he had for some time experienced, and he found it necessary to have recourse to the waters of Bohemia, from which he derived great benefit. But his wife was attacked with a nervous fever, in consequence of her attendance on the deserted sick; and although she recovered, Fichte, whose affection would not allow him to leave her for a moment, caught the infection, and died on the 29th of January 1814.

Fichte was small in stature, but stout and well-formed; his countenance was expressive of thoughtfulness and determination. In his intellectual character, genius was combined with inflexible firmness; and these qualities enabled him to surmount difficulties which would have overwhelmed a less vigorous temperament. In other respects his dispositions were amiable, and his morals correct. It was in the academical chair that the genius of Fichte was manifested in its greatest splendour. It was said of him that he was born a professor; and there was, indeed, a charm in his manner of lecturing which had a powerful influence on the minds of his pupils, several of whom we have heard talk of him with enthusiasm. His fervid and brilliant eloquence, the clearness of his reasoning, and the simplicity and correctness of his language, seemed to diffuse a magic light and colouring over the darkest and most abstruse metaphysical problems. Those who were charmed with his eloquence, were easily convinced by his reasoning, and became willing converts to his doctrines. His writings, especially those works in which his peculiar doctrines are propounded in a systematic form, are by no means so attractive as his lectures appear to have been. On the contrary, notwithstanding a constant affectation of strict and simple reasoning, his propositions are enveloped in such a degree of transcendental obscurity, as renders it extremely difficult to comprehend either the basis or the scope of that system of doctrines which he labours to establish.

Hence, it is far from being an easy matter to give an intelligible abstract of the principles of the *Doctrine of Science*, especially as we must necessarily presuppose some acquaintance, on the part of our readers, with the previous metaphysical labours of Kant. Fichte commenced his philosophical career precisely at that period when the writings of Kant had nearly obtained a paramount influence in the German schools, and when men even of superior talents thought it no mean glory to be able to comprehend and illustrate his doctrines. The Kantian theory was confessedly idealistic. Its celebrated author set out with an analysis of the cognitive faculty, endeavoured to describe its various functions, and to ascertain the scope and limits of its legitimate exercise. All our knowledge, according to the critical philosophy, must have a reference to possible experience. Of external objects, or things in themselves (*noumena*), we can have no absolute knowledge; for we can know nothing but what is perceived by the senses, and cognized (if we may be allowed the expression) by our intellectual faculties, according to the laws peculiar to our constitution. These intellectual laws, or subjective forms, tend to combine our knowledge, and to render the field of experience a comprehensible whole. As we can have no knowledge of objects in themselves, but only of their *phænomena;* neither can we have any knowledge of things beyond the sphere of our experience, because these can neither be perceived by our senses, nor subjected to the laws of the understanding. All reasoning, therefore, from mere ideas must necessarily be futile, because it has no reference to any corresponding object within the limits of experience. And although we can have no absolute knowledge of objects as they really exist, yet our knowledge of them possesses a subjective reality (i. e. a reality with reference to the thinking subject), and may be said to correspond with the objects, because, from the nature of our intellectual constitution, we are incapable of receiving any other impression from them.

Reinhold was one of the earliest partisans of Kant, and one of the most ingenious and most popular commentators on the critical philosophy. But his talents were better adapted for explaining and illustrating the doctrines of others, than for discovering new truths, or inventing any original system of his own; and although an indefatigable student of philosophy, he seems to have never arrived at any settled conviction in metaphysical matters, but to have alternately adopted and abandoned every new theory which was successively presented to his view. After having been, for some time, enthusiastically devoted to the doctrines promulgated in the *Critical Review of Pure Reason*, which he esteemed the greatest masterpiece of philosophical genius; he at length discovered that Kant had neglected to secure the foundations of the edifice he had raised, and this defect he attempted to supply by his own *Theory of the Faculty of Perception.* (*Theorie des Vorstellungsvermögens.*) The main proposition laid down and illustrated in this work is nothing more or less than this: We are compelled by consciousness to admit, that every perception presupposes a percipient subject and an object perceived, both of which must be distinguished from the perception to which they relate;—thus referring all our knowledge to consciousness as its ultimate principle. In the enunciation of this proposition there is nothing very new or original; but the illustration of this elementary doctrine, which, as a late reviewer of the German metaphysical theories observes, might have formed an excellent subject for a short philosophical dissertation of two or three sheets, is dilated into a work nearly as large as that to which it was intended to serve as a mere introduction; nor is the unnecessary length of the treatise in any measure compensated by the importance of the truths developed, or the ingenuity displayed in the research.

With greater talents and consistency, Fichte, who announced himself as a strict Kantian, attempted to solve the same problem, and to develope a system, which, by deducing all our knowledge from one simple principle, should give unity and stability to the critical theory. In his *Doctrine of Science* (*Wissenschaftslehre*), accordingly, he derives all our knowledge from the original act of the thinking subject in reflecting upon itself. *I am I*, (which he expresses by the formula $A = A$), or the absolute position of the I by the I, is in itself the certain principle of all philosophy and of all our knowledge. But the creative energy of the I, in the course of this reflective process, goes still farther. By its own act, also, the I places the *not—I* (objects) as opposed to itself. In reflecting upon itself, as the absolutely active principle, it finds itself either determined by, or determining the *not—I.* In the former case, it appears as the *intelligent I;* in the latter, as the *absolutely free, practical I.* Hence the distinction between theoretical and practical philosophy. The idea, then, which pervades the whole theory of Fichte is this: The I, or the thinking subject, is the absolutely active principle, which *constructs* the consciousness, and produces all that exists, by position, contra-position, and juxta-position. The whole universe, in short, is the product of the I, or thinking subject.

We have thus endeavoured to give a very concise sketch of a theory, which we shall not think of pursuing through its various ramifications, as we should despair of making it intelligible to our readers by any length of exposition. Fichte has been praised by his countrymen for his logical and consistent reasoning; but to us it appears that his theory proceeds entirely upon arbitrary assumptions, resting upon no solid foundation. That he displays considerable ingenuity in the developement of his ideas we are willing to admit; but we are quite at a loss to perceive the merit of the theory he has advanced, when considered as a system of philosophical truths. The parade of scientific deduction which his reasoning exhibits may impose upon the incautious student; but a careful examination will undoubtedly convince him, that the whole is a mere tissue of empty notions, drawn from arbitrary and assumed principles.

In attempting to apply the principles of his doctrine of science to the theory of morals and the law of nature, Fichte exhibited many original and paradoxical opinions, along with some very just and ingenious philosophical observations. In his later writings he considerably modified his original theory of the doctrine of science, and produced a system of philosophical and religious mysticism, which appears to have given birth to the transcendental idealism of Schelling; an author who seems to have carried the extravagance of speculative reasoning to its utmost limits.

The following is a list of the works of Fichte:

1. *Versuch einer Kritik aller Offenbarung.* (Critical Review of all Revelation.) Koningsberg, 1792, 1793. 8vo.

2. *Ueber den Begriff der Wissenschaftslehre.* (On the notion of a Doctrine of Science.) Jena, 1794. 8vo.

3. *Grundlage der gesammten Wissenschaftslehre.* (Foundation of the whole Doctrine of Science.) *Ibid.* 1794. 8vo.

4. *Grundriss des eigenthümlichen der Wissenschaftslehre.* (Sketch of the peculiarity of the Doctrine of Science.) *Ibid.* 1795.

5. *Vorlesungen ueber die Bestimmung des Gelehrten.* (Lectures on the Literary Calling.) Jena, 1794.

6. *System der Sittenlehre.* (System of the Doctrine of Morals.) Jena and Leipsic, 1795.

7. *Beyträge zur Berichtigung der Urtheile des Publicums ueber die Französische Revolution.* (Materials for Rectifying the Opinions of the Public respecting the French Revolution.)

8. *Grundlage des Naturrechts.* (Foundation of the Law of Nature.) Jena, 1796, 1797. 2 Vols. 8vo.

9. *Appellation an das Publicum ueber die ihm beygemessenen atheistischen Aeusserungen.* (Appeal to the Public respecting the Atheistical expressions imputed to him.) Jena and Leipsic, 1799.

10. *Ueber die Bestimmung des Menschen.* (On the Destiny of Man.)

11. *Der geschlossene Handelsstaat.* (The exclusive Commercial State.)

12. *Sonnenklarer Bericht an das grössere Publicum ueber das eigentliche Wesen der neuesten Philosophie.* (Luminous Report to the greater public on the peculiar Character of the Modern Philosophy.) Berlin, 1801.

13. *Wissenschaftslehre.* (Doctrine of Science.) Tübingen, 1802. 8vo.

14. *Vorlesungen ueber das Wesen der Gelehrten.* (Lectures on the Literary Character.) Berlin, 1806.

15. *Die Grundzuge des gegenwärtigen Zeitalters.* (The Characteristics of the present age.) *Ibid.* 1806.

16. *Anweisung zum seligen Leben.* (Guide to a Happy Life.) *Ibid.* 1806.

17. *Reden an die Deutsche Nation.* (Discourses to the German Nation.) *Ibid.* 1806.

18. *Die Wissenschaftslehre in ihrem allgemeinsten Umrisse dargestellt.* (The Doctrine of Science exhibited in its most general outline.) *Ibid.* 1810.

19. *Freidrich Nicolai's Leben und Sonderbare Meinungen, herausgegeben von Schlegel.* (Life and singular opinions of Frederic Nicolai, edited by Schlegel.) Tübingen, 1801.

20. *Antwortschrieben an K. L. Reinhold, auf dessen Beyträge zur leichtern Uebersicht des Zustandes der Philosophie,* &c. (Answer to K. L. Reinhold, on his Materials for acquiring a more easy view of the State of Philosophy, &c.) *Ibid.* 1801.

21. *Ueber die einzig mögliche Störung der academischen Freyheit.* (On the only possible disturbance of Academical Freedom.) Berlin, 1812.

22. *Ueber den Begriff des wahrhaften Kriegs, in Bezug auf den Kreig in Jahre* 1813. (On the notion of real war, with reference to the war in 1813.) Tübingen, 1815.

Fichte is also the author of several essays in periodical publications, and particularly in a philosophical journal edited by himself, with the assistance of Niethammer.

Those who are desirous of obtaining more minute information respecting Fichte's philosophical theory, may consult the following works: Tennemann's *Grundriss der Geschichte der Philosophie;* Degerando, *Histoire Comparée,* &c. W. T. Krug, *Briefe ueber die Wissenschaftslehre.* F. W. J. Schelling, *Darlegung des wahren Verhältnisses der Naturphilosophie zu der verbesserten Fichtischen Lehre.* J. Fries, *Reinhold, Fichte und Schelling.* C. F. Bachmann, *Ueber die Philosophie meiner Zeit.* Ancillon, *Essai sur le premier probleme de la philosophie;* and *Essai sur l'existence et sur les derniers systemes de metaphysique qui ont paru en Allemagne.* (H.)

Situation and Extent.

FIFESHIRE is bounded by the river Tay on the north, the German Ocean on the east, the Frith of Forth on the south, and on the west by the counties of Kinross, Perth, and Clackmannan. Its medium length, from east to west, is about 36 miles, and its breadth, from north to south, 14; so that its area is 504 square miles, or 322,560 English acres. About four-fifths of this may be considered as fit for cultivation, and the remainder consists of hills, mosses, and moors, with roads and plantations.

Surface and Natural Divisions.

This county, which is situated on the south-east corner of the middle peninsula of Scotland, is, for the most part, composed of low lying grounds, though little of it is flat or level. There is a pleasing variety of hill and valley in every direction. It is divided into two parts by a tract of high ground, which comprehends the Lomond Hills on the west, and from thence stretches forward almost in a direct line till it approach within a few miles of the sea. The highest of these hills is West Lomond, which is 1721 feet above the level of the sea; Largo Law, on the east, is 952, and Kelly Law 810. The rivers Eden and Leven throw it into three divisions, the northern, between the Eden and the Tay, the middle, between the Eden and the Leven, and the southern, between the Leven and the Frith of Forth. Along the Frith of Forth, from the eastern to the western boundary of the county, the land rises gently, and has no great elevation above the sea. The soil here is generally very fertile, for a breadth of about three miles, a deep rich loam, or clay, and sometimes loam with gravel. Beyond this, a cold poor clay prevails, lying, for the most part, on sandstone, which extends northward to the high ground on the south of the Eden. In this district there are extensive tracts of moss and moor. Farther north, on both sides of the Eden, and from the mouth of that river westward to Perthshire, there is a rich valley called the *How* of Fife, which spreads out as it approaches the sea into a considerable tract of very productive land. A range of high grounds, a continuation of the Ochills, intervenes between this valley and the Tay on the north; yet as the soil lies upon whinstone it is in many places fertile, and often deeper and richer on the acclivities than at their bottom.

Climate.

As no part of Fifeshire is nine miles from the sea, the climate is mild and the harvests early. Snow seldom lies long. Yet from the direction of its hills, from east to west, it is much exposed to the easterly winds, which often check vegetation in the spring months; and hoar frosts are not unfrequent so late as the middle of June. The heaviest rains are from the south-west, the south-east, and the north-east, and the winds from the two last points bring the greatest falls of snow. The driest and most steady weather comes from the west, north-west, and east.

Waters.

The only streams of any note are the *Leven* and the *Eden*. The former, which issues from Loch Leven, in Kinross-shire, flows eastward through a beautiful strath, by Leslie, Balgonie, and Balfour, and, after a course of about twelve miles, during which it receives the Lothrie and the Orr, falls into the Frith of Forth at the town of Leven. From the declivity of its channel, it is well fitted for impelling machinery, and accordingly a great number of mills have been erected on its banks. It abounds in salmon and sea trout, and where it falls into the sea, there is a considerable salmon-fishery. The Eden is formed by the confluence of several small streams in the parish of Strathmiglo on the west, near the boundary with Kinross-shire, and winding slowly through a level valley, and sometimes overflowing its banks, passes the town of Cupar, and loses itself in the German Ocean, about eighteen miles from its source. It contains trout, pike, and eels, and has also a salmon-fishing where it discharges itself into the sea. The Gair Bridge over this river, consisting of six arches, was built in the beginning of the fifteenth century. There is a number of lochs, none of them large, but some of them very beautiful, such as those at Lindores, Kilconquhar, Kinghorn, Lochgellie, Camilla, Lochfittie, and Otterstone.

Coal.

The southern part of Fifeshire, from the Forth almost to the Eden, abounds in coal of all the kinds common in Scotland. Along the Frith of Forth the strata generally dip to the east and south-east, but are cut off before they reach the higher ground, not extending above two or three miles from the shore. In this district, proceeding from west to east, coal is found in the parishes of Torryburn, Abbotshall, Kirkaldy, Dysart, Wemyss, Scoonie, Largo, and Pittenweem. The coal-works in Dysart and Wemyss are very considerable; in the former parish there is a bed eighteen feet thick, which is said to have been wrought more than 300 years ago, and it is remarkable for having been frequently on fire. Beyond this tract to the north, the coal and all the other strata commonly incline to the north or north-east. The most considerable collieries in this quarter are in the parishes of Dunfermline, Dalgety, Auchterderran, Leslie, and Markinch; the last of which only resembles the metals on the sea-coast in its general bearing.

Limestone.

Limestone is in great abundance along the whole of this tract. In the Saline hills, still farther to the north, coal and lime are found in various places; there is a considerable coal work at Keltie, in the parish of Beith, on the borders of Kinross-shire; but from the south side of the vale of Eden northward to the Tay, there is no coal nor any appearance of the metals that usually accompany it, except perhaps near Newburgh, where limestone occurs. From a charter, dated in March 1291, it would appear that coal has been wrought in this county for more than five centuries. William de Oberville there grants liberty to the convent of Dunfermline to open a coal pit in his lands of Pittencrieff. But this is not, as has been alleged, the first instance of a Scottish charter containing a right to work coal; for Mr. Chalmers alludes to one dated in 1284-5, from which it may be inferred, that coal was wrought on the lands of Tranent before that period. The greatest lime-works in Scotland are at Charlestown, on the Forth, belonging to the Earl of Elgin; about 100,000 tons are raised here annually, part of which is sold as it comes from the quarry, and 12,000 tons of coals are employed in calcining the remainder on the spot. Ironstone, of a good quality, is found in the parishes of Dysart and Dunfermline, and sandstone in almost every part of the coal district. Lead has been wrought in the Lomond hills. Marl is met with occasionally, and clay fit for bricks and tiles; at Durie coal-works, a species of clay has been discovered proper for fire-bricks. Stones, somewhat resembling the precious garnet, are found in considerable numbers at Elie, and known by the name of *Elie rubies*.

Estates.

Most of this county is divided into estates of a moderate size; there are a greater number, indeed, above L.400 Scots of valuation than in any other county in Scotland; but of the 626 estates which it contained in 1811, 491 were below that amount. In the same year the number of freeholders, entitled to vote for a member of the county, was 207. If

Fifeshire. we may judge from the valuation, which is still the rule for the payment of cess and other taxes, Fifeshire must have been the most valuable of all the Scottish counties about the middle of the seventeenth century; **Rental.** the amount is L.363,192, 3s. 7$\frac{1}{12}$d. Scots, almost a tenth part of the whole valuation of Scotland. Somewhat more than a third of this belongs to estates held under entail, and there are twenty-nine estates belonging to corporate bodies, which, like the former, cannot be brought to market. The rental of the lands, in 1811, was L.[illegible] Sterling, or almost a guinea an acre over the whole, and of the houses L.38,756, [illegible]. On the Lomond hills, there is a common of about 4000 acres, one of the very few now to be found in Scotland, which once belonged to the palace of Falkland, and afterwards became the property of the surrounding heritors; yet it was thought not to come under the Scots statute, authorising the division of commons, which excepts those belonging to the King and to royal burghs, and lay still in its natural state; but having been divided very lately, it will soon be rendered much more valuable. **Seats.** There is a great number of elegant seats in the county, of which ten belong to eight peers, and seven to baronets, besides more than seventy to other proprietors. According to the author of the Agricultural Survey, published in 1800, upwards of [illegible] sterling had been expended on buildings during the twenty-four years preceding. Considerable tracts have been planted within these last [illegible] years; yet there is still a want of shelter in many parts, and the county at large is by no means well wooded.

Ancient Buildings. Fifeshire is also distinguished for its buildings of an ancient age. Among the [illegible] the most remarkable are the ruins of the [illegible] Andrews, said to [illegible] century; the [illegible] 1159; the Abbey of [illegible] Robert Bruce, [illegible] interred with [illegible] Lindores, [illegible] Pittenweem; and [illegible] Falkland, originally [illegible] Fife, and afterwards [illegible] the castles of Rosyth, [illegible] Ravenscraig, [illegible] Wemyss, Balgonie, and [illegible] the seat of Sir Thomas [illegible] to Charles I. [illegible]

Caves. [illegible] people, [illegible] old style, but [illegible]

pied by their proprietors, and others by manufacturers, tradesmen, and mechanics. In all the new leases the rent is made payable in money, though in a few instances the amount may depend upon the price of grain, and vary from year to year accordingly. The common endurance of a lease here, as throughout Scotland, is nineteen years. It was usual formerly to add the life of the tenant, under the idea that he would always hope to live a little longer, and thus continue to improve his farm, instead of exhausting it, as is too commonly done towards the end of a lease, when it is for a number of years certain; but this expectation has seldom been realized, and the practice of adding the life has therefore been discontinued. Farm-buildings present a great variety in regard to their materials and construction as well as their size; but such as have been recently erected are not unsuitable to the extent of the farms; and the cottages are generally better now than many of the best farm-houses were fifty years ago. More than a third of the county is completely and substantially enclosed with dry-stone walls or thorn hedges, chiefly the latter; the rest is either altogether open, or so badly fenced as to afford neither security nor shelter; the hedges, in too many instances, being full of gaps, and overgrown with weeds.

Agriculture. Of the agriculture of Fifeshire, it is only necessary to observe, that all the farm-crops common in the south of Scotland are cultivated here upon a large scale, for the greater part according to the most approved system, and with great success; and that this is one of the few Scottish counties where flax is grown to some extent as a farmer's crop; though it is by no means a favourite with landlords, who, in some instances, have prohibited the tenants from sowing more than one acre in a year. **Cattle.** The cattle of this county have long been in high repute, both as feeding and dairy stock. The prevailing colour is black; horns small, white, turned up at the points; bones small in proportion to the carcase; weighing, when fat, from three to four years old, from 40 to [illegible] stones. The cows, when well fed, yield from 10 to 14 Scots pints of milk daily (nearly half as many English wine gallons) during the best of the grass season, and [illegible]; yet the dairy is here but a secondary object. The oxen were formerly much employed in tillage and were in request for this purpose for the [illegible] but they are now very seldom to be seen at work. There are very few flocks of sheep. The [illegible]

Manufactures. [illegible]

Fifeshire.

the manufacture in 1800 was computed to be 28,192. Flax is spun into yarn almost in every family, and, since 1793, a number of mills have been erected, which supply yarn for the coarser fabrics. The other manufactures are spirits, at four distilleries, one of which works for the English market; shipbuilding at Dysart, Kirkaldy, Wemyss, and Anstruther; salt at the two former places and other towns; leather at Kirkaldy, Cupar, Auchtermuchty, and Falkland; and there are breweries in every town, and most of the villages. At Cupar, Kirkaldy, and Leven, bricks and tiles are made to a large amount; and vitriol or sulphuric acid at Burntisland. Haddocks, cod, and in their season herrings, are caught in considerable quantities on the coast, and part of the salmon fishings on the Tay belong to this county.

Commerce.

Though the situation of Fifeshire, almost surrounded by the sea, with several harbours, which, at a small expense, might be made to admit vessels of great burden, is particularly favourable for commerce, yet it makes no figure in that department. Customhouses are established at Kirkaldy and Anstruther, the former of which embraces all the coast from Aberdour to Largo, and the latter from Largo to St Andrews. The trade on the north side of the county is under the inspection of the customhouses of Dundee and Perth, and that from Aberdour westward belongs to the customhouse of Borrowstownness. In 1800, 142 vessels, carrying 13,512 tons, and navigated by 883 seamen, were under the two customhouses within the county, and about half the number of each was supposed to be under those out of it. These vessels are partly employed in foreign trade with Russia and the ports on the Baltic, but chiefly in the coasting trade. The exports are the manufactures already mentioned, with coal, lime, and grain of all sorts; and the imports from foreign parts, timber, bark, hides, and tallow, flax and flaxseed, hemp, tar, iron, &c. and coastwise, groceries, and other articles required for home consumption.

Royal Burghs.

Fifeshire contains seventeen royal burghs, four of which were excused from sending representatives to Parliament, from their inability to defray the necessary expences, but still retain all their other privileges. The thirteen which have a share in the election of the members for the Scotch burghs are Burntisland, Kinghorn, Kirkaldy, and Dysart, which form one district; and Anstruther, East and West, Pittenweem, Kilrenny, and Crail, another. The remaining four are joined with burghs belonging to other counties; Cupar and St Andrews, with Dundee, Perth, and Forfar; and Dunfermline and Inverkeithing, with Stirling, Culross, and Queensferry. Fifeshire thus sends three members to Parliament, one for the county, and two for its burghs; besides, that the latter have a share in the election of two members more. None of these towns are now considerable, Dunfermline excepted, which is a thriving place, with a population, in 1811, of 11,649. That of Cupar, the county town, and St Andrews, the two next in importance, is about [illegible]; Kirkaldy 3747, and all the others less than 2000. Packets and ferry-boats ply regularly across the Forth from several of these places; but the great thoroughfares are between Leith and Kinghorn, or Pettycur, and between Queensferry and Inverkeithing or the North Ferry.

Parishes.

Fifeshire is divided into sixty-one parishes belonging to the four presbyteries of St Andrews, Cupar, Kirkaldy, and Dunfermline, which compose the synod of Fife; but there are four parishes besides in the presbytery of Dunfermline, and one in the presbytery of Kirkaldy, which are not situated in this county. The population in 1801 and 1811 will be seen from the following abstract. See Sibbald's *History of Fife and Kinross.*—Thomson's *General View of the Agriculture of the County of Fife.*—*The Beauties of Scotland*, Vol. IV.—*The General Report of Scotland*, 1814; and Playfair's *Description of Scotland*, 1819. FILANGIERI (Gaetan), celebrated for his various works on political economy and legislation, was born at Naples, on the 18th August 1752. He was the third son of Cesar Prince of Anianello, by Marianne Montalto, daughter of the Duke of Fragnito. His family was ancient, and rose to distinction at the first establishment of the Neapolitan monarchy. Angenio, its founder, was the son of one of those brave Normans who landed in Italy about the beginning of the eleventh century, and accompanying Count Roger in all his military expeditions, he received from him ample domains as the reward of his exploits. His descendants were allowed to take the honourable title of Filii Angerii, and hence the name Filangieri. Gaetan from his infancy was destined to the profession of arms; when he was seven years of age, he was enrolled in one of the royal regiments, and he commenced actual service at the age of fourteen. His education was at first neglected from a misconception of his character, which was supposed to be averse from all literary or speculative pursuits. The injudicious methods adopted at that time in the teaching of Latin had, it appears, disgusted him, and alienated his mind from the study of this language; and hence an impression had been hastily taken up of his general unfitness for all literary exercises. A lucky accident, however, not only removed this apprehension, but showed that his former impatience of the modes of tuition then in use, arose from the clearness and vigour of his judgment. It happened that his brother's preceptor had one day mistaken the solution of some geometrical problem. Gaetan immediately perceived the source of this error, which he demonstrated to the master. This incident, apparently trivial, determined his future destiny. Encouraged by his success he quitted the military service, and determined to follow his natural taste for science and philosophy. So diligent was he in repairing the defects of his education, that at twenty years of age he had acquired a knowledge of Greek and Latin, of ancient and modern history, of the great principles both of civil and of public law, and was besides well initiated in mathematical science. Although his genius inclined him solely to the study of legislation and policy, he sacrificed his views to the wishes of his friends, and entered on the profession of the law, which was then the certain road both to honour and fortune. His success was rapid both from his eloquence and his extensive knowledge; and, about this period, a circumstance happened which greatly conduced to his celebrity. Great abuses prevailed at Naples in the administration of justice from the uncertainty of the law, which gave rise to constant misconceptions, and almost always to arbitrary judgments. By a wise ordinance of the King, passed in the year 1774, at the suggestion of the minister, Tanucci, those abuses were reformed, the law was restored to its proper authority, its judgments were freed from the control of precedents, and the judges were ordained, in every case, to publish the grounds of their decisions. Although this reform was generally applauded, it excited the murmurs of the bar. Filangieri now became the advocate of the court, and published a defence of the royal decree, founded on the most enlarged views of equity and reason. The extensive knowledge and matured judgment displayed in this performance attracted the attention of the ministers, and Filangieri was encouraged to pursue the course in which he had already acquired such distinction. Through the influence of his uncle, the Archbishop of Palermo, he was, in 1777, placed in an honourable office at court, and was almost at the same time named officer of the royal corps of marine volunteers, who were more particularly attached to the king's person. His abode at Court neither broke in upon his regular habits of life, nor upon the course of his studies; nor did he allow it to interrupt the composition of the great work on legislation and government in which he was engaged, and to which for several years past he had devoted all his inquiries. About the commencement of the eighteenth century, a great school of philosophy was formed at Naples, in which the principles of the civil law, of the law of nations, and of legislation, were established on the solid and comprehensive basis of general expediency. From this school numerous works of celebrity have proceeded, among others the great work of Beccaria, which, though confined to one branch of legislation, contains general principles which are of universal application. There was still wanting, however, a general treatise on legislation, for the purpose of examining it in all its relations, and of laying down some common and universal principles of equity and expediency as its only true basis; and it was to this important undertaking that Filangieri's philosophical mind was directed. His subject he proposed to divide into seven books. The first, on the general rules of legislation, and the second on political laws, and on those laws also which are connected with the general structure of society, appeared in 1780 at Naples; and such was its popularity, that not only in Italy, but throughout Europe at large, the author was ranked among the most celebrated writers on public law. According to his theory, the goodness of laws is either absolute or relative. It is absolute, when they are agreeable to those great and universal principles of equity and expediency which are obligatory on man under every diversity of country, climate, government, or manners; it is relative, according as the laws agree with the nature of the government, with the genius and character of the people, with the climate, with the fertility or sterility of the soil, with the physical circumstances of the country, with the religion of the inhabitants, and the degree of civilization to which they have advanced. In his second book, which treats of political laws, and of those laws also which are connected with the general economy of society, he examines two points, namely, the state of population and of wealth. With respect to the first point, the great question which he considers is, whether Europe is as populous as it might be? This question he resolves in the negative, and he proceeds to explain the causes of this deficient population. According to his hypothesis, the state of agriculture affords in every country the surest evidence as to the state of the population; and the backwardness of agriculture in most parts of Europe sufficiently indicates that the population is deficient; and hence he infers the defective state of European legislation on these two capital points. The great obstacles to the improvement of agriculture, and, consequently, to the increase of population, he considers to be, *1st,* The small number of proprietors and the great number of non-proprietors. *2dly,* Too many large properties, and too few small properties. *3dly,* The exorbitant and inalienable possessions of the church in several states. *4thly,* The excess of the public imposts, and the violent modes of levying them. *5thly,* To these he adds other causes of less importance, such as the state of most of the regular troops of the European states; also public corruption and the dissoluteness of private morals. The progress of agriculture, the great source of wealth as well as of population, may also be obstructed by a bad political administration, by bad laws, or by those causes which occasion a great influx of inhabitants to the respective capitals of the different states. It belongs to a pure system of legislation to remove some of those obstacles, and to counterbalance such others as are inevitable, by suitable encouragements. Having discussed those momentous questions, he enters into a comprehensive survey of the other sources of riches, namely,—arts, manufactures, and commerce,—and points out how they may be obstructed by a faulty legislation, and, at the same time, the means by which these might be removed. In order fully to comprehend the merits of these performances, we must consider that all the faults which the author reprehends were committed by his own government; a circumstance which imposed on him the delicate task of stating obnoxious truths with freedom and boldness and, at the same time, without offence. So well, however, did he appreciate the views of those whom it was his wish to enlighten, that he was immediately promoted by the king to the Commandery in the Royal Order of Constantia. In 1783, he married a Hungarian lady of noble birth, who was entrusted with the education of the second daughter of the king, and who joined to outward attractions the gift of a sound judgment and an agreeable disposition. That he might the more freely enjoy domestic happiness, and, at the same time, have leisure for the composition of his work, on which he became every day more intent, he resigned, with the consent of the king, all his military employments and his office at court, and retired to a country seat about twenty miles from Naples. In the same year, he published his third book, relating entirely to the principles of criminal jurisprudence. In these discussions he maintains the same tone of decision and independence as before. Abuses are freely pointed out, and the defects of the penal code, and in the forms of criminal procedure, are fairly exposed. In thus pointing out those defects in the domestic administration of his government, Filangieri excited the hatred of an interested and powerful class; and a proposition which he made in his third book, for the reformation of abuses in the Roman Church, drew down upon his work the censure of some of the ecclesiastical tribunals. In 1785, however, he published the 5th, 6th, and 7th volumes of his work, which comprehended his fourth book. These were devoted to the consideration of education, morals, and public instruction; and though, on these important points, we may be occasionally disposed to question his views, we must nevertheless admire his mild and philosophical spirit still opposed to every excess, his extensive knowledge, and his happy talent of arranging and combining it for the illustration of his argument; his animated, flowing, and perspicuous style; and, above all, that rectitude and philanthropy which is diffused over all his reasonings. His fifth book was soon after published, which treated of the laws relative to religion. His health was now considerably impaired, owing to an excess of application, so that the remainder of his work advanced but slowly; and other interruptions soon followed. In the year 1787, he was called by the new king, Ferdinand IV., to the supreme Council of Finance. He returned to Naples, and from that time was wholly engrossed with the important business of this office. His health, already impaired, was soon completely broken by such severe and active application, and several domestic misfortunes operating upon a mind of deep sensibility, threw him at last into a state of melancholy. He finally retired from all business into the country, where he soon after fell seriously ill, and on the 21st July 1788 he expired. Before his death he had finished the 8th volume of his work, containing the first part of the 5th book, in which he treats of the different systems of religion which preceded Christianity. Of the second part of the same book he had only made a rude sketch, in which were noted down the principal subjects of discussion; namely, the advantages of Christianity and the dangers of superstition; the inconveniences of mixing spiritual with temporal concerns; the excessive riches of the clergy, and the immense increase of their power. He was also to examine the foundation of ecclesiastical rights, and to present, in a new system of legislation, a remedy for the abuses which he pointed out. A chapter on toleration would have terminated this book. In his 6th and last book he proposed to treat of the laws relative to property, and of the nature of the paternal power and the government of families. He had also other important works in contemplation when his course was terminated by death. This eminent person, along with the rarest gifts of genius, was endowed by nature with the additional advantage of a most imposing presence. His manners were graceful and dignified. His countenance bore the traces of habitual reflection, and of deep sensibility, mingled with an expression of soft melancholy. In private life nothing could exceed the simplicity of his character, and the animation and interest of his conversation.—See *La Scienza della Legislazione.* 5 Tom. 8vo. Livour. 1807. This is the last Italian edition of Filangieri's great work. There is a French translation in 7 vols. 8vo, published at Paris in 1798, from the Neapolitan edition of 1784. The *two first Books* have been translated into English, under the title of *The Science of Legislation,* from the Italian of Filangieri, and published in 2 vols. 8vo. Lond. 1806. (o.)

FISHERIES.

Fisheries.

In the body of the *Encyclopædia* will be found some details on the British fisheries, the laws by which they are regulated, the various kinds of encouragement they have met with from the government, and private individuals, and some account of their state up to the period when that article was written. It is now proposed to take a more general and extended view of this important branch of employment, to point out what is conceived to be the real causes which have impeded its progress, and to give a general sketch of the present state both of the home and foreign fisheries.

HOME FISHERIES.

Alleged neglect of by Great Britain.

The alleged neglect of the fisheries, on the part of Great Britain, has been the subject of unqualified censure, from a very early period of her naval and maritime history, and reproaches have been dealt out with no sparing hand, not only for having disregarded those advantages, so liberally bestowed by Nature along the extensive coasts of her sea-girt islands, in supplying a wholesome and nutritious article of food for the sustenance of an abundant population; but also, for suffering the nations of the Continent to resort to her very bays and harbours without molestation, and even purchasing from them that very property which she was either too ignorant or too indolent to procure by her own sagacity or industry; though neither of them required to be exerted in any extraordinary degree, in the pursuit of this occupation. "The fishery," says Sir William Monson, "needs no discovery; the experience of our neighbours having found it out, and practised it since the year 1307, to their immeasurable wealth and our shame."

Contrasted with the attention of the Dutch.

Thus also, Sir John Boroughs complains in his *Sovereignty of the British Seas*, that "it maketh much to the ignominy and shame of our English nation, that God and Nature, offering us so great a treasure, even at our own doors, we do, notwithstanding, neglect the benefit thereof, and by paying money to strangers for the fish of our own seas, impoverish ourselves to make them rich;" and as a contrast to our supposed indolence and indifference, he draws a lively picture of the bustle and activity which the herring fishery of Holland communicated to the various tradesmen and artificers, labourers, salters, packers, &c. and of the multitude of poor women and children to whom it afforded employment. In a little pamphlet, under the title of *England's Path to Wealth and Honour*, in a dialogue between an Englishman and a Dutchman, the whole alphabet is ingeniously brought to bear, in regular order, on the trades and occupations connected with the herring fishery of Holland. The importance, indeed, of this branch of national industry in that country is pretty obvious from the following abstract of the population of the States-General taken in 1669.

Persons employed as fishermen and in equipping fishermen with their ships, boats, tackle, conveying of salt, &c.	450,000
Persons employed in the navigation of ships in the foreign trade, wholly independent of the trade connected with the fisheries,	250,000
Persons employed as manufacturers, shipwrights, handicraft trades, dealers in those manufactures, ...	650,000
Persons employed in agriculture, inland fishing, daily labourers, ...	200,000
Inhabitants in general not included in any of the above, ...	650,000
Idle gentry, without calling, statesmen, officers, soldiers, beggars, &c. supported by the labour of the rest, . .	200,000
Making a total of	2,400,000

Importance of the Herring Fishery to the Dutch.

From which it will appear not at all improbable that the pensionary De Witt did not exaggerate when he stated, that every fifth man earned his subsistence by the sea fishery; that Holland derived her main support from it; and that the herring-fishery ought to be considered as the right arm of the republic. It is further asserted that, when in the zenith of her prosperity, not less than 3000 boats, of various kinds, were employed in the bays and islets of her own coasts; and that, in those of Great Britain, they had 800 vessels, from 60 to 150 tons burden, occupied generally in the cod and ling fishery, besides others employed in carrying out salt to them, and returning with cured fish; that from Bouganess to the mouth of the Thames, they had a fleet of 1600 busses actively engaged in the herring fishery, each of which might be said to give employment to three others in the importation of foreign salt—in carrying the salt to fishing ships, and returning with cured fish—and in the exportation of that fish to a foreign market;—making, thus, the total number of shipping engaged in, and connected with, the herring fishery alone, to amount to 6400 vessels, calculated to give employment to 112,000 mariners and fishermen. By the same authority we are told that Holland, at that time, could boast of 10,000 sail of shipping, and 168,000 mariners; "although the country itself affords them neither materials, or victual, or merchandise, to be accounted of towards their setting forth." Indeed, the Dutch themselves made no scruple of avowing, that the wealth, strength, and prosperity of the United Provinces were derived from the herring fishery; the importance of which was strongly marked by an observation in common use among them, that "the foundation of Amsterdam was laid on herring-bones."

No wonder, then, that the example of the Dutch should be held forth as a reproach to England; and we find, accordingly, that it was so considered by some of the ablest writers of former times, Sir Walter Raleigh, Sir William Monson, Sir William Petty, Sir Roger L'Estrange, and others. It would seem, however, to have altogether escaped these writers, that the situation and circumstances of the Dutch were entirely different from those in which the people of the British islands were placed. Those provinces of Holland, where the fisheries flourished, had few or no resources but those which the waters afforded them; they grew no corn; they had no superabundance of food for the rearing of cattle; they had few or no manufactures; whereas Great Britain had all, and abounded in most of them. The Dutch having, therefore, neither food nor raiment but what they must purchase from foreign nations, and the only article they had to offer in return being the products of the seas, it was necessary for them to expend their whole industry in availing themselves of those products, in order to exchange them for others of the land. It was not, therefore, from choice, but absolute necessity, that the Hollanders braved the dangers, and submitted to the fatigues, of the deep sea fishery. It was their whole resource, and afforded them the only scope for turning their industry to profit; and it must be allowed that, by an extraordinary degree of patience, and of perseverance, and, by long practice, they succeeded in bringing to a state of unrivalled perfection the mode of catching and the method of cure, which other nations, less experienced, and less interested, had not arrived at; though it is now known, and admitted, that there is no great art nor mystery in the craft,—nothing that British fishermen could not then have, and, in point of fact, nothing which they have not of late years, accomplished, in as perfect a manner as the Dutch.

Circumstances different between England and Holland.

But the case was different with regard to Great Britain. She laboured under none of the disadvantages, and felt none of the necessities, which pressed upon Holland. Her capital was employed in foreign commerce, in the improvement of her agriculture, and in the introduction of some and the perfection of other branches of manufacture. The complaints, therefore, of the indolence of the British; of their buying fish from the Dutch rather than choosing to undergo the risk and fatigue of catching them, even on their own shores, will not, perhaps, on due consideration, appear to be well-founded. Their conduct may be ascribed rather to the very natural result of being able to employ their capital in a more lucrative, a more pleasing, and less precarious way. It would be too much to expect that he, who can buy a fish for half the money required to catch one, will quit his present employment and turn fisherman; or that he, who can make a greater and more certain profit in commerce, agriculture, or manufactures, than by fishing, will divert his capital from the former to embark in the latter. The government had repeatedly held out encouragement for the pursuit of the fisheries; and aided the efforts of individuals in various ways to promote the success of a branch of national industry of so much importance to the national wealth and strength. Liberal subscriptions for this purpose have, at various times, been set on foot; privileges and immunities have been granted; villages built at the public expence; and ships and boats with all the necessary articles and tackle, supplied; premiums have been conferred, bounties granted, duties exempted, the fishermen have been protected from the impress, and those who may have followed the occupation for seven years allowed to set up, and freely exercise, any trade or profession, in any town or place of Great Britain.

Encouragement given to the Fisheries.

The failure, therefore, could not always have been owing to want of protection and encouragement; though it may, in some measure, to the want of knowledge or circumspection in the way of administering it. Neither could it be ascribed to the want of funds. In 1580, a plan was matured for raising L.80,000 for establishing the British fishery. In 1615, the same sum was raised by a joint stock company. In 1632, a royal fishing company was established, by the sanction of King Charles I., who, in order to increase the demand, prohibited the importation of foreign fish, directed a supply to be furnished for his fleet, and ordered Lent to be more strictly observed. In 1660, Parliament granted a remission of the salt duties, and freed all the materials employed in the fisheries from customs and excise. In 1661, the national fishery met with great encouragement under the auspices of Charles II. In 1677, this monarch incorporated the Duke of York and others into "The Company of the Royal Fishery of England;" but, on this occasion, the miserable capital was exhausted in the purchase and fitting out of a few busses, built in Holland, and manned with Dutchmen, which were seized by the French on the breaking out of the war. In 1743, it was proposed to raise L.180,000 on annuities, for the purpose of establishing a fishing company. In 1749, by the recommendation of George II., in his opening speech to Parliament, and, in consequence of a Report of a Committee of the House of Commons, the sum of L.500,000 was subscribed for carrying on the fisheries, under a corporation, by the name of "The Society of the Free British Fishery," of which the Prince of Wales was chosen the governor. This society, patronised by men of the first rank in the kingdom, promised fair for a little time, but soon began to languish; nor was the large bounty of 36s. a ton able to prevent its total failure. The attention of Parliament was again called to this great national object in 1786, when a new corporation was formed, under the name of "The British Society for Extending the Fisheries and Improving the Sea Coasts of the Kingdom," which has continued, with various modifications, to the present time; and, as we shall presently see, has been of late years in a flourishing and progressive state of improvement.

Present impediments to the progress of the Fishery exaggerated.

Thus, then, it is evident that we must look for the real grounds of the general languishing state of the British fisheries, in other causes than those which have usually been assigned by our ancestors; and though the complaint, in modern times, may have some foundation, which is almost exclusively levelled against the salt duties, and, after these were wholly removed, against the numerous checks and excise regulations, which are stated to be as grievous and discouraging as were the duties themselves; yet the impediments which these are alleged to throw in the way of the improving state of the fisheries, have probably been much exaggerated. There can be no doubt that much benefit would be derived from a total repeal of all the acts relating to the duties and the regulations of salt; and yet, when the old writers stated their grievances, the article of salt is never once mentioned. In fact, there were then neither duties nor restrictions on this article of universal use; and yet the fisheries did not flourish under the free and unlimited use of it.

The salt-duties originated as a *war tax* in the ninth year of William III.; and in the first year of Anne, a regular salt code was established, and confirmed by five several statutes in the same reign. George I. and II. added but little to the salt-laws; but the present reign, as Sir Thomas Bernard observes, has "greatly *enriched* the code by voluminous and contradictory clauses, sometimes in the form of guards to the revenue, sometimes in the semblance of bounties, drawbacks, and allowances, surrounded by pains and penalties, oaths and perjuries, and so extended and involved, as to be quite beyond the comprehension of those who are peculiarly affected by them:" he adds, that "since his Majesty's accession, no less than thirty acts have been passed on the subject of these duties, and not less than 300 pages of additions made to our *saline-code*." Sir Thomas, as an active member of "The Association for the Relief of the Manufacturing Poor," took great pains to ascertain the bearing which the duties and regulations on salt had on agriculture, manufactures, and the fisheries. His conclusion, with regard to the latter, is, that the act of 57th Geo. III. which permits an unlimited allowance of rock-salt, duty free, though it may not come within the reach of the poor solitary fisherman, will benefit those whose capitals are engaged on a larger scale. This act, also, by increasing the allowance of duty-free salt on *dry-salted* cod, ling and hake to 70 lbs. *per* cwt. of fish, which, by a former act (55th Geo. III.) was limited to 50 lbs. is stated to have had a salutary effect on these fisheries. As a proof of this, it is mentioned, that, on its being understood, at the time of passing this latter act, that the duty-free allowance was to be fixed at 70 lbs. the persons concerned in the *North Sea and Iceland fisheries*, who were preparing to take advantage of it, immediately abandoned the enterprise on finding the blank filled up with 50 lbs. of salt per cwt. of fish.

The restrictive regulations for securing the duties on salt, and for the prevention of fraud on the revenue, were necessarily vexatious and severe in a case where those duties were equal to forty times the value of the original article, and the temptation consequently great in proportion. But their operation, [illegible] is [illegible] by the [illegible], though it still continues to affect the [illegible] fisherman, who cannot afford [illegible] salt, for which he is accountable, [illegible] to waste, and which he may [illegible] have occasion to use. Every one [illegible] that the total repeal of the salt laws would be a great boon to the whole community, but equally [illegible] that, in the present state of the country, the revenue could ill afford to be diminished to the extent of L.1,500,000. If Parliament would consent to a commutation of 5 *per cent.* on all houses of and above the annual rent of L.20, it would probably make good this sum, and would deserve the thanks of the whole community.

The salt laws, however, operate only as a very partial discouragement to the prosecution of the fisheries; and not at all, as already observed, where they are established and conducted on a grand scale. What then, it may be asked, is the real cause of our fisheries not being carried on to a greater extent, at a time when provisions are dear, and work not to be found for multitudes of the labouring classes of the community? It certainly is not that the government is indifferent of, or insensible to, the political importance of the fisheries. It has not only at different times held out such encouragements as were deemed conducive to the end in view, but shown itself so jealous of the interference of our neighbours, as to attempt to establish an appropriate and exclusive fishery in all the seas surrounding our coasts. Thus James I., in 1609, issued a proclamation inhibiting all persons of what nation or quality soever, not being natural born subjects, from fishing upon any of the coasts and seas of Great Britain and Ireland, and the isles adjacent, without first obtaining licences from the King, &c. But this, as well as the repetition of it by Charles I., in 1636, was utterly disregarded by the Continental powers. To enforce this measure, the Duke of Northumberland, as Admiral of the Fleet, was sent into the North Sea to compel the Dutch fishermen to take licences, and pay for the same, but the Ambassador of the States-General in England remonstrated against this unprecedented proceeding, and disavowed the acts of their fishermen.

The attempt to set up a limited fishery, and to prescribe boundaries to the prohibited grounds, met with no better success; but they showed, at least, a desire to prevent the advantages derivable from this element, from falling into the hands of others. It is probable, however, that these claims were set up with the view rather of maintaining the title of the sovereignty of the seas, than from any contemplation of the national advantages derivable from the encouragement of the fisheries; and more especially for the purpose of preventing any encroachments on the part of the Dutch and French.

Real Caus
of the Bac
ward State
of the I[illegible]
eries

The simple fact we take to be this; that the success of the fisheries, like that of every other speculation, must depend mainly on the two great hinges on which all commercial enterprises turn—supply and demand: where these exist to any great extent, and without any material fluctuation, the success of a fishery establishment cannot be doubtful. If, however, the supply be not equal to the demand, the article [illegible] danger of falling into the hands of [illegible] practice is to add to the [illegible] the price. By thus [illegible] supply within its natural limits, they [illegible] the demand. [illegible] the expenditure, and the adventurers withdraw their capitals, and turn them into some other channel. But a certain and steady demand creates competition, and regulates the supply to the wants of the consumer at a fair and reasonable price.

Want of Steady Demand.

It is the want, we conceive, of this steady and constant demand, and not of supply, which has at all times operated to the discouragement of the British fisheries. That the supply of fish is most abundant, and indeed inexhaustible, on the coasts of Great Britain, has never been called in question. " The coasts of Great Britain," says Sir John Boroughs, " doe yield such a continued sea-harvest of gain and benefit to all those that with diligence doe labour in the same, that no time or season in the yeare passeth away without some apparent meanes of profitable employment, especially to such as apply themselves to fishing; which from the beginning of the yeare unto the latter end, continueth upon some part or other upon our coastes, and these in such infinite shoales and multitudes of fishes are offered to the takers, as may justly move admiration, not only to strangers, but to those that daily bee employed amongst them." That this harvest, ripe for gathering at all seasons of the year—without the labour of tillage, without expence of seed or manure, without the payment of rent or taxes—is inexhaustible, the extraordinary fecundity of the most valuable species of fish would alone afford abundant proof. To enumerate the thousands, and even millions of eggs which are impregnated in the herring, the cod, the ling, and, indeed, in almost the whole of the esculent fish, would give but an inadequate idea of the prodigious multitudes in which they flock to our shores; the shoals themselves must be seen to convey to the mind any just notion of their aggregate mass. The herring, for instance, makes its appearance in shoals, whose dimensions are measured by leagues and miles, moving steadily along in close array, and in columns of such depth from the surface downwards, as to have obtained the name among the northern nations of *herring mountains*. These columns advance yearly from the northern seas, early in the spring, with undiminished numbers, though preyed upon by a multitude of enemies, as well from the shore, as in their native element and in the air. Wherever their vast columns proceed, if unmolested by man, they have to sustain constantly the attacks of the grampus, the porpus, the shark, cod-fish, and even haddocks; and if they approach the surface, they are seized by the innumerable flocks of sea-gulls, gannets, and other aquatic fowls, which hover along their line of march. Where the spawn of the herring is usually deposited, naturalists seem not to be agreed; but as young herring have not been caught either with the old ones, or within the limits of the fishery, and as the shoals invariably proceed from the northward, making their first appearance about the Shetland Islands in the month of April, it has generally been thought that their winter habitation is within the arctic circle, under those vast fields of ice which cover the northern ocean, where it fattens on the swarms of shrimps, and other marine insects, which abound in those seas, and which afford also the principal food of the whale. Here it is supposed they deposite their spawn, and, on the return of the sun toward the northern hemisphere, again rush forth in those multitudinous hosts, which exceed the power of the imagination to conceive.

The pilchard, which is a species of the same genus as the herring, is also a migratory fish, but makes its appearance from the southward, in vast shoals, inferior only to those of the former; which is also the case with the mackerel, both being of equal or greater fecundity with the herring, and liable to the attacks of the same enemy. The salmon is equally irregular in its visits to the coasts of Great Britain and Ireland, and approaches the mouths of our rivers in shoals, which they ascend to considerable distances, surmounting every obstacle, in order to find a safe and convenient spot to deposite their innumerable eggs. The various kinds of white fish, as turbot, sole, plaice, whitings, and haddocks, are plentifully dispersed over various parts of the British seas, affording an inexhaustible supply of fresh fish for home consumption throughout the whole year, without the least apprehension of such supply being exhausted or diminished. On the eastern shores of Great Britain, and on the rocky coasts of the Orkney and Shetland Islands, are plenty of lobsters, which would more than supply the market of the metropolis with this article of luxury, as the south-eastern and southern coasts do the oyster with its nutritious food for eight months in the year.

Use of Fish scarcely known in the interior.

In spite, however, of this abundant supply of wholesome, palatable, and nutritious food, yielded by the surrounding seas of Great Britain, every acre of which is infinitely more productive than the same quantity of the richest land; notwithstanding that these salt-water fields are perpetually " white to harvest," it is a remarkable fact, that in the inland and middle counties of England, the labouring classes scarcely know the taste of fish, which, of late years, has become a scarce article, even in most of the maritime counties. Formerly salmon was the common food of all ranks, while in season, in the northern counties abounding on the sea, and in most parts of Wales; and what could not be used fresh, was salted for winter consumption; scarcely a family in the neighbourhood of a sea-port or salmon fishery that did not lay up a supply of pickled salmon for the winter. In the progress of luxury, well-boats were invented to convey the fish fresh to the London market, yet these were not sufficiently numerous to carry off the whole supply. The next contrivance was that of packing them up in ice, by which they could be kept fresh for a length of time, and conveyed either by land or water to the metropolis: since which the local markets have nearly been left without a supply, even for the few families who can afford to pay an extravagant price for it. That price in London is greatly enhanced, by the trade being almost exclusively in the hands of monopolists, who have it at all times in their power to create an uncertainty in the supply, and consequently a fluctuation in the price, both of which are detrimental to an augmented demand.

London monopoly and its Effects.

That a narrow confined corner, at the very extremity of the metropolis, should continue to be allowed the privilege of absorbing all the fish that shall be brought within the radius of seven miles round its vortex, is an extraordinary fact, and but ill accords with the boasted good sense of these enlightened times. It needs scarcely be mentioned, that Billingsgate is this favoured spot; holding by charter an injurious and hateful privilege, which, as Sir Thomas Bernard justly observes, "in the greatest and most populous city in the world, restricts the sale of an essential article of life to a small and inconvenient market; and has exclusively placed the monopoly of fish in the hands of a few interested salesmen." The consequence of which is, that a sort of *blockade* checks the supply of fish for the metropolis; that large quantities are withheld or destroyed as they approach the market in order to keep up the price; and 2,000,000 of people nearly prohibited from the use of an article of food, which might be applied to the diminishing of the consumption of butchers' meat and wheat-corn, to the great relief of the whole kingdom. The tricks and abuses practised by the fishermen, the salesmen, and the fishmongers, who act in concert, are well calculated to create a scarcity, even if perchance more fish should arrive than are sufficient to feed the market; their object being to prevent the prices from descending one particle below the point of the smallest profits in their sale. In order to effect this, they have generally a depot of well-boats and store-boats ready stocked about Gravesend; and with these, and the assistance of a good stock of ice, they are enabled to dole out their fish for the daily use of those who have the means to purchase, and who form but a small proportion of the inhabitants of the metropolis. In the height of the season of any particular species of fish, when the catch is abundant, such of them as get sickly are thrown over-board; but towards the end of it, when, from increasing numbers, a large stock remains on hand, and other kinds come into season, thousands of sickly and emaciated lobsters, crabs, cod-fish, &c. are thrown into the market, hawked about by basket women, and sold somewhat cheaper when they are no longer fit to be eaten.

The "Committee of the Fish Association" have stated some curious particulars with regard to the practices of the fish monopolists, and the injurious effects of confining the fish-market to one little spot in the metropolis. They reckon up four principal impediments to an increased supply and distribution, of which they strongly recommend the removal by all practicable means. The first, which, in fact, produces the rest, is the restriction of the market to Billingsgate; the second is the doubt and hesitation of fishermen in bringing up to this only market so large a quantity of fish as they might procure, under an uncertain demand for it; the third, the difficulty and the increased expence of distribution from their above-mentioned remote market; and the fourth, the uncertainty of the price, and the total ignorance in which the public are kept as to the *daily state* of the supply.

The evils of the Billingsgate monopoly are strongly exemplified in the case of mackerel, which is known to be scarcest in the market, when most abundant in the British channel: then, indeed, the mackerel fishery is abandoned by the fishermen for two reasons; the one is, that they would be too cheap; the other, the difficulty of distribution, which is effected by fisherwomen, who attend daily at Billingsgate to purchase the mackerel, and carry them for sale to the different parts of the town; the attendance of these women secures to the fishermen a regular custom for their fish; but this laborious, and not always profitable employment, is abandoned as soon as the common fruit comes into season, the carriers and distributors finding the sale of strawberries, gooseberries, currants, &c.—a more pleasant and profitable occupation, with less risk and trouble. All the mackerel which may arrive at this period beyond the estimated demand of the fishmongers, however fresh and good, is thrown into the Thames. Perhaps, therefore, in the case of this particular fish, a free and unrestricted use of salt might be the means of procuring and preserving a considerable stock of palatable and nutritious food.

It is the more surprising that these impediments to a more extended use of fish in the metropolis, so obviously arising out of the chartered privilege of Billingsgate, should so long have been suffered to exist, especially as nothing more is required for the dissolution of this injurious monopoly, than the establishment of new markets. The evils of this monopoly are not of recent date. In early times, there appears to have been a regularly established fish-market at Queenhithe. In the first year of Henry III. (1226), the Constable of the Tower was ordered to compel the boats, arriving with fish, to proceed to that market; and Edward IV. directed that two out of three vessels arriving with fish, should proceed to Queenhithe, and the other remain at Billingsgate. At that period, the population of London and its environs appears to have been about a twenty-fourth part of its present amount, yet it had then two fish-markets. The market of Queenhithe, however, was suffered to drop; and we hear of no attempt to establish a second, until the middle of last century, when an act was passed, in the year 1749, "for making a free market for the sale of fish in the city of Westminster, and for preventing the forestalling and monopolizing of fish." Yet, strange and unaccountable as it may appear, this act was then, and has since remained, a dead letter. Westminster, since that time, has increased its population at least three-fold, and is still without a fish-market. The act has never been repealed, and requires only the nomination of new and more efficient commissioners to carry it into effect. If, in the vicinity of all the bridges across the Thames, fish-markets were once established, the fishermen of Deal, Dover, Hastings, Brighton, and other parts of the coasts of Kent and Sussex would amply supply those markets by land-carriage, with the ordinary kinds of fish in addition to the more valuable kinds brought up the Thames; and it could not fail to increase the general use of fish in and about London, if, when the Regent's Canal shall be opened, two or three fish-markets were established near it for the supply of Islington, Pancras, Paddington, and the whole line of London along the new road, containing an immense population almost entirely cut off from the use of fish. The only arguments in favour of keeping back the fish, and throwing them overboard, is the frequent westerly wind which prevents the fishing-vessels from proceeding to the market up the Thames; but that excuse is now done away by the numerous steam-vessels which could easily tow up the fishing-boats.

Demand should be created to take off the supply

The supply, as we have stated, is inexhaustible; and the means are within our reach of availing ourselves to any extent of that supply; but the demand appears obviously to be neither so steady and certain, nor so extensive, as it might and ought to be; and hence the real cause of the failure of all the plans for extending the fisheries. When the catch was abundant, the fishermen had no home market to take the fish off their hands; and a bad season impoverished the funds of those who had embarked on a larger scale for the foreign market. The promoters, dissatisfied, withheld their contributions; and the fishermen, dispirited, and without capital, directed their industry into another channel; and too frequently, from their knowledge gained of the opposite coast, and new connections formed there, into a channel destructive to their morals and injurious to the revenue.

Observations on the Bounties

The encouragement given by the government in the shape of bounties, was not sufficient to counteract the evils that have been stated, and appears to have contributed but little to the success of the fisheries. If a branch of trade once fairly established will not support itself without being bolstered up by bounties, it never can be worth carrying on. Bounties should only be continued for a definite time, and decreased gradually. Those on the fisheries should be given on the quantity procured, and the quality of those cured, and not on the instrument of their production—on the fish, and not on the vessel. It was proved by a Committee of the House of Commons, in 1785, that the herring-fishery absolutely cost little short of L.20,000 annually, which, on an average of ten years, was equal to L.75 *per cent.* on the value of all the fish that had been taken by the vessels on which it was paid. Adam Smith has justly observed, that a tonnage-bounty, proportioned to the burden of the ship, and not to her diligence and success in the fishery, is not the best stimulous to exertion; it was an encouragement for fitting out ships to catch, not the fish, but the bounty; or to induce rash adventurers to engage in concerns which they do not understand, and cause them to lose, by their ignorance, more than is gained by the liberality of Government. The carelessness of such persons, and the ignorance of those employed by them in curing and packing the fish, not only robbed the public purse, but destroyed the character of the article in the foreign market; where, if saleable at all, it fetched only an inferior price, while the skill and attention of the Dutch secured for their fish that preference to which they were justly entitled. The change of the bounty, however, from the tonnage to the quantity and the quality of the fish caught and cured, with the regulations adopted by the acts of 48th and 55th Geo. III. have had the good effect of raising the character, and consequently increasing the demand for British fish in the foreign markets, where the herrings in particular are now held in equal esteem with those of the Dutch. This bounty, granted by the act 48th Geo. III. c. 110, is 2s. *per* barrel on all herrings branded by the proper officers, and 4s. a barrel granted by the act 55th Geo. III. c. 94, and is so considerable, that, at this time, it amounts to a sum not less than L.30,000 a-year.

Nothing can more strongly exemplify the good effects arising from the measure of shifting the bounty from the tonnage to the actual quantity of fish taken, gutted, and packed, than the following official return, for the year ending 5th April 1818:

AN ACCOUNT of the Total Number of Vessels, including their repeated Voyages, which have been cleared Outwards for the British Herring-Fishery, *not on the Tonnage Bounty*, in the year ended 5th April 1818; distinguishing the number of Men on Board, the Tonnage, Netting, Salt, and Barrels carried out.

Vessels.	Men.	Tonnage.	Netting.	Salt.	Barrels.
Number.	Numb.	Tons.	Sq. Yards.	Bushels.	Number.
881	4,049	26,951 $\frac{12}{94}$	2,490,660	224,133	125,185

THE RETURN, for the same year, of the Total Number of Vessels which were fitted out in Scotland, for the "Open Sea Fishery," under the Regulations of the 48th and 55th Geo. III., is as under:

Vessels.	Tonnage.	Men.	Netting.	Herrings	Premiums Paid		
Numb.	Tons.	Numb	Sq. Yards.	Barrels.	*L.*	*s.*	*d.*
19	464 $\frac{86}{94}$	139	191,628½	946½	1308	0	0

Experiments showing the possibility of extending the Demand.

It would appear, therefore, that all which is now wanting for the encouragement and extension of the British fisheries is a constant, steady, and increased demand, in the home and foreign markets. An experiment made by Mr Hale, one of the members of the committee for the relief of the manufacturing poor, proves decisively how easy it would be to introduce the general use of fish in the metropolis. He agreed with some fishermen to take from ten to twenty thousand mackerel a day, at a price not exceeding 10s. the hundred of six score, or at a penny a-piece, a price at which the fishermen said they could afford to supply the London market to any extent, provided they were sure of a regular sale. On the 15th June 1812, upwards of 17,000 mackerel were sent to Spitalfields, and sold at the original coast of a penny a-piece, to which place women were employed to carry them from Billingsgate until eleven o'clock at night. They were purchased with avidity, and vast numbers continued to pour into Billingsgate. They were sent to other parts of the town, and sold to the poor at the same rate; and it is stated that "the supply increased to so great a degree, that 500,000 mackerel arrived and were sold in one day." The whole cost of this experiment for the distribution of fresh and sweet mackerel at a penny a-piece, was L.55, 10s. expended chiefly in the carriage from Billingsgate. In like manner, it is estimated that herrings might be supplied in any quantity at one halfpenny a piece, and cod, haddocks, whitings, flounders, &c. proportionally cheap, provided a steady demand was created, as it is presumed there would be, by the establishment of several regular markets in different parts of the metropolis.

Another experiment of the committee shows how easily a demand for salted or corned fish might be created in the inland counties. They contracted for 209 tons of corned cod, caught and cured on our own coast, and also for 400,000 corned herrings. The former was supplied to the distressed manufacturers of Sheffield at twopence half-penny a pound, and the latter at the rate of two for three halfpence. Here, as well as in other parts of the country, the poor, it is stated, received the fish distributed among them at low prices with the liveliest gratitude; and one gentleman in Worcestershire states that "The herrings, in particular, have proved a bonus to the poor of the most essential benefit. We sold them," he says, "at a very low and reasonable rate, on account of the extreme indigence of the purchasers; and they have produced L.40 (profit), which, after the expence of carriage is paid, will be laid out in employing the poor in repairing the roads."

It deserves to be mentioned, as an instance of the certainty of a supply to answer the demand, that, when the "Association" was formed in 1812, the North Sea and Iceland fishery had for some time entirely ceased; but, on the Committee offering the fishermen L.18 a ton for all the fish they should catch and cure, they supplied, in the first instance, 100 tons of dry-salted, and 50 tons of fresh cod. In the second, 200 tons of dry-salted, and 100 tons of fresh. In the third, 600 tons of dry-salted, and 300 tons of fresh; in all 1350 tons of fish were taken and brought to market in consequence of this offer, not a fish of which would otherwise have been caught.

The obvious policy, then, to be pursued for extending the British fisheries, is by creating an extended and constant demand. In the foreign markets this can only be done by the care and attention bestowed in curing the fish, so that, in point of quality, it may compete with those of the Dutch and other nations of the Continent; a point which we have just now happily attained; but in the supply for home consumption, every thing almost yet remains to be done. The *Fish Association* have, however, clearly shewn the way of proceeding to obtain this desirable end; they have proved that, not only in the metropolis but in the interior of the country, the poor have none of those prejudices, which were ascribed to them, against the use of fish, when it is fresh and sweet, and when they are able to procure it at a moderate price. A free circulation, by means of markets established in the metropolis and at all the fishing ports, might effect this to a certain degree; but, in addition to these, some artificial expedients might be advisable, for a time at least, to raise and keep steady the demand. It is much to be regretted that Queen Elizabeth, who was well aware of the importance of the fisheries, in a political as well as economical point of view, did not, in regulating the church ritual, ordain two days in every week to be set apart by Protestants as fish days, which would have created a steady and permanent demand for fresh and salted fish in every part of the United Kingdom. Such an ordinance might, in her reign, have been enforced, and long habit would have reconciled people to the observance of those days in our times; but it would be in vain to attempt the introduction of any such custom in the present refractory generation. There seems, however, to be no good grounds of objection to those who are maintained at the public expence being fed twice a-week, with a wholesome meal of fish. It is neither just nor politic that, while the poor labouring man, after toiling the whole week, can scarcely procure a little brown bread and a few potatoes for his wife and children, the indolent pauper should feed on the best white bread and choice butchers' meat. Supposing the number of paupers receiving parish relief, of convicts in the hulks, criminals in the jails, and, in short, all those who are fed at the public expence, to amount only to 1,000,000; and that to each was served out, twice a-week, a sufficient allowance of good fresh fish, corned cod, or salted herrings, according to the season of the year and the situation of the parties, which could be amply provided for the value of three-pence a-head, the annual demand of fish, from this source alone, would amount to the sum of L.1,300,000. The voluntary consumption of the labouring poor would be at least equal, could an adequate supply be obtained at a cheap rate; and that it might will readily be inferred, when it is stated that, in the herring season, these fish may, on an average, be purchased at the stations for sixpence a hundred, and the salt required to cure them costs about one penny. Supposing the whole expence of a hundred to be one shilling, and one shilling more for land carriage to the farthest point in the interior; and allowing the retailer a profit of 100 *per cent.*, a good salted herring might still be purchased for one halfpenny, and two herrings, with a few potatoes, would furnish a wholesome palatable meal. Salted or corned cod would be supplied almost equally cheap; and thus the quantity of food for the subsistence of man would be greatly increased, the fisheries encouraged, the consumption of butchers' meat lessened, and more pasturage converted into corn-lands, by which the enormous sums of money which are annually sent out of the country for the purchase of foreign corn would be employed at home. At present we have to trust for a supply of this "staff of life" to a miraculous plenty or a ruinous importation.

Political importance of the Fisheries.

It would be superfluous to dwell on the political, economical, and commercial importance of encouraging and improving the fisheries, to an insular empire like ours. We shall only observe, that, by their augmenting the quantity of food, there would necessarily result a reduction in the prices of all the necessaries of life; the condition of the labouring poor, the artificers, and trades-people, would as necessarily be improved; they would not only be the means of rearing and supporting a bold and hardy race of men for the defence of the sea-coast, but, also of creating a nursery of excellent seamen for the navy in time of war, and of giving them employment when peace may render their further services unnecessary. If the fisheries flourished to that extent of which they appear to be capable, every seaport town and little village on the coasts, or on the banks of the creeks and inlets, would become a nursery of seamen. It was thus in Holland, where the national and natural advantages were very inferior to those of Great Britain; for it is well observed, in the *Report of the Downs Society*, that Holland produces neither timber, iron, nor salt, all of which are essential to fisheries, and all the natural produce of Great Britain; that Holland has no herrings on her own coast, while the coasts of our island abound with them and other fish, at different and all seasons of the year; so that there are few, if any, months in which shoals of this fish in particular are not found on some part of our shores; and that her population is under 3,000,000, while ours amounts to about 18,000,000, giving to our fishermen six times the consumption of a home market that the Dutch have.

Though the occupation of a fisherman is dangerous, laborious, and precarious, yet it does not appear that the want of sufficient hands has at any time retarded the progress of the fisheries. At this moment 30,000 seamen, receiving pensions from L.7 to L.20 and upwards, according to their wounds, infirmities, and length of service, are located for the most part along the sea-coasts of the united empire, all of whom, not otherwise employed in the coal and coasting trade, would readily add to their little pittance they receive from a grateful public, by being employed on an element so congenial with their habits.

Actual progress of the British Herring Fishery.

With all the impediments to an extended use of fish in the home market, and notwithstanding the established character which the Dutch fish have always borne among foreign nations, it is consoling to find that the British fisheries are generally in a progressive state of improvement, and more particularly that most important of all their branches, the herring fishery. Since the act of 48th Geo. III., appointing commissioners, separate and distinct from the Customs and Excise, to superintend the distribution of bounties, stationing of officers versed in the trade of the herring fishery, persons who had experimentally and practically followed that fishery as a trade, but who are excluded from all interest or participation in the trade, the herring fishery has become with us as it was with the Dutch, an object of national concern; the good effects of which are most sensibly felt in every part of the coast, where it has regularly been established, by the labour it provides, the demand it creates for a variety of articles required by it, and by the money it throws into circulation. By this act, an annual report by the commissioners, of their proceedings, ending the 5th April, is required to be presented to Parliament each session; containing the details of the fishery of the preceding year, together with such observations and suggestions as may have occurred, or been communicated to the commissioners, in the interval between the reports. In the report of the year ending 1814, they had stated, "that the superior value of herrings, branded by the officers of the fishery, in point of quality, weight, and measure, was becoming every year to be more generally acknowledged, even in markets where, till of late, gutted herrings were not much prized; and this they ascribe to their refusal of every application for allowing bounty on barrels out of the full size of 32 gallons, and to their having directed prosecutions against the proprietors of such herrings, as had been seized for being presented for bounty in undersized barrels; and that, with other precautions respecting the proper cure of the herrings, the desired effect had been produced, of raising the character of British herrings in the foreign market." In their report of 1816, they state that they have had their attention turned to different matters calculated to improve the cure of herrings, and to raise the character of the British fishery in foreign parts; that a communication, made to them by a mercantile house of respectability, on the subject of increasing the exportation of herrings to the Continent of Europe, had been printed, and distributed among the curers throughout the kingdom; that regulations had been adopted for improving the construction of barrels intended for bounty; that the boats of the fishermen had been properly fitted up for the reception of herrings; that bounty had been refused on all barrels not full of pickle; and that the strictest orders had been given to the officers of the fishery, to apply the official brand in no case, unless both herrings and casks were in every respect such as would do credit to the establishment. In the year 1817, the commissioners point out in their report the great increase that had taken place in the exportation of British herrings to the Continent of Europe, in consequence of the communication made to and the regulations adopted by them, as contained in the preceding report; and, in the year 1818, they observe that they had received a memorial on the subject from Hamburgh, signed by a number of herring merchants of that port, bearing testimony to the improvement that had taken place in the quality of British herrings, and pointing out the means of raising their character still higher. This memorial the commissioners likewise caused to be printed, and distributed among the curers, which they accompanied with such additional observations as they conceived to be necessary, and which they state to have produced the most salutary effects. They conclude their statement with the gratifying intelligence, that the character of the British fishery is rising both at home and abroad; for that, while the quantity of herring cured *gutted* is annually increasing, the quantity cured *ungutted* is every year diminishing;

that great as the amount of the fishery had been in the course of that year, the demand had fully kept pace with it; and that, at the end of the season, few herrings remained unsold in the hands of the curers. They further report, that while the exportation to the Continent of Europe had nearly equalled that of the preceding year, and the exportation to the West Indies and Ireland had increased, a new market had opened in the East Indies, to which different shipments of herrings had been made, by way of experiment, both from Greenock and London: that, from the former of these places, upwards of 1300 firkins were exported to Calcutta, all of which they understood were purchased by Europeans there at 20s. to 25s. *per* firkin; and that it was the intention of the exporter, in consequence of this encouragement, to ship a larger quantity next season; so that the commissioners trust, that India will soon become a permanent and valuable market for the consumption of British herrings. The report thus concludes, "It is impossible to state, within the compass of this report, the advantages resulting to the community from the prosperity of the herring fishery; but the commissioners think it their duty briefly to mention that the effects thereof are felt in almost every part of the kingdom. The fishermen have, in many cases, been enabled, by the produce of their industry, to replace the small boats formerly used, by new boats of much larger dimensions, and to provide themselves with fishing materials of superior value. The number of boats and of fishermen has been greatly increased; while, by the general introduction of the practice of *gutting*, a valuable source of employment has been opened to thousands of poor people, who now annually resort to the coast during the continuance of the fishing season, and there earn a decent livelihood in the operations of gutting and packing. New dwelling-houses and buildings, on a superior construction, for the curing and storing of the herrings, are erecting at almost every station along the coast; while the demand for home wood for the manufacture of barrels, affords a source of profit and employment to numbers of people in the most inland parts of the country."

The progress of the herring-fishery will best be seen by a summary view of the quantities *caught*, *cured* for bounty, and *exported* in the last three or four years.

By the report of 1815, it appears that the quantity cured *gutted* was 105,372¼ barrels. By that of 1816, it amounted to 135,981 barrels, being an increase in one year's fishery of 30,608¾ barrels.

The quantity cured *ungutted*, in the former period, was 54,767 barrels; in the latter 26,670¾ barrels, being a decrease of 28,096¼ barrels.

The total quantity brought under the view of the officers in 1815 was 160,139¼ barrels. In 1816, it was 162,651¾ barrels; being an increase, on the whole, of 2,512½ barrels.

The quantity branded for bounty in 1815 was 83,376 barrels. In 1816, it was 116,436, being an increase of 33,060 barrels.

The exports, on the whole, in 1815, exceeded those of 1816; but the *gutted* herrings exported in the latter year exceeded those of the former by 12,606½ barrels.

In the year 1817, the total quantity caught was 192,343½ barrels, being an increase of 29,691¼ barrels. In the same year, the quantity branded for bounty was 140,018½ barrels, being an increase of 23,582½ barrels. The quantity exported in 1817 was 138,628½ barrels, being an increase of 30,940½ barrels.

In the year 1818, the total quantity caught was 227,691 barrels, whereof 204,270½ were cured *gutted*, and 23,420¾ *ungutted*; being an increase in the total quantity of 35,347½ barrels, and of 48,494¼ in the quantity gutted; while there was a decrease in the quantity cured *ungutted* of 13,146¾ barrels.

In this year, the quantity found entitled to bounty was 183,089½; being an increase of 43,071 barrels. In the same year, the total quantity exported was 162,339½ barrels, whereof 148,147½ were *gutted*, and 14,192 *ungutted*; being an increase in the total quantity of 23,711 barrels, and of 32,667 in the quantity *gutted*; while there was a decrease in the quantity *ungutted* of 8,956 barrels.

But the report of the year ending 5th April 1819 is still more flattering than any of the former ones, as will be seen from the following ACCOUNTS, which exhibit at one view the state of the herring fishery at the different stations in Great Britain, under the superintendence and control of the commissioners, and the officers appointed by them.

No. I.

AN ACCOUNT of the Total Number of Barrels of White Herrings, which have been landed from the Fishery, or Cured on Shore, in the Year ended 5th April 1819;—in so far as the same has come under the Cognizance of the Officers of the Fishery.

L.105, 3s., L.83, 8s., L.96, 8s., and L.148, 3s. They were manned by four men each, so that they made, on an average, rather more than L.27 a man. In 1815, the number of boats employed amounted to 50, almost entirely manned by Sutherland men; and the number of barrels caught and repacked exceeded 4000, chiefly gutted. In 1817, this fishery gave employment to about 200 tenants, 17 coopers, and 130 women. In 1818, 70 coopers, 520 women, 700 men, 140 boats; and, in the present year (1819), the quantity caught and cured at Helmsdale, as appears by the Table, amounts to no less than 22,876 barrels, besides upwards of 100,000 cod and ling. While the herring-fishery is making these rapid strides in the Highlands of Scotland, the ancient town of North Yarmouth, which owes its existence to the herring-fishery, and in the time of Edward III. had an act usually called "the statute of herrings," passed in its favour, for the regulation of its herring-fair, now exhibits only the small number of 1039 barrels.

White-Fishery.

But not only does North Britain take the lead in the herring-fishery, but has of late, more than before, availed herself of her favourable situation for carrying on that branch which may be reckoned next, perhaps, in importance to it, namely, the cod and ling fishery. The whole extent of sea, from the neighbourhood of the Orkney and Shetland Islands to Iceland on the one hand, and to the coast of Norway on the other, and along the eastern and western shores of Scotland, to the Flemish banks on the east and the coast of Ireland on the west, may be considered as one great fishing domain, over which the different species of the cod genus are most plentifully dispersed; as are also turbot, skate, soles, haddocks, and whitings. These fish, which constitute collectively what is usually called the *white fishery*, surround, as it were, the whole of North Britain, and give to that portion of the united kingdom advantages which its southern neighbours cannot boast of.

Turbot-Fishery

The only fishery, perhaps, which neither the Scotch nor the English follow up with equal success as the Dutch, is that of the turbot, the finest of which are supposed to be taken on the Flemish banks. The turbot-fishery begins about the end of March, when the Dutch fishermen assemble a few leagues to the south of Scheveling. As the warm weather approaches, the fish gradually advance to the northward, and, during the months of April and May, are found in great shoals on the bank called the *Broad fourteens*. Early in June they have proceeded to the banks which surround the small island of Heligoland, off the mouth of the Elbe, where the fishery continues to the middle of August, when it terminates for the year. The mode of taking turbot is as follows: At the beginning of the season, the drag-net is used, which, being drawn along the banks, brings up various kinds of flat fish, as soles, plaice, thornbacks, and turbots; but, when the warm weather has driven the fish into deeper water, and upon banks of a rougher surface, where the drag-net is no longer practicable, the fishermen have then recourse to the hook and line. Each line extends from one to nearly three miles in length, and is armed with six, seven, or eight hundred hooks, fixed to it at the distance of several yards from each other. To keep these long lines properly stretched, and prevent their being carried away by the tide, heavy masses of lead in some places, and small anchors in others, are attached to them. The hooks are baited with the common smelt, and a small fish resembling an eel, called the gore-bill. Though very considerable quantities of this fish are now taken in various parts of our own coasts, from the Orkneys to the Land's End, yet a preference is given, in the London market, to those caught by the Dutch, who are supposed to have drawn not less than L.80,000 a-year, for the supply of this market alone; and the Danes from L.12,000 to L.15,000 a-year, for sauce to this luxury of the table, extracted from about one million of lobsters, taken on the rocky shores of Norway; though our own shores are, in many parts, plentifully supplied with this marine insect, equal in goodness to those of Norway.

Salmon Fishery

Scotland has very decidedly the advantage over England in the salmon-fishery, which, if not of superior value, may be allowed to rank next in importance to the cod-fishery. This fish being rarely caught except in estuaries or rivers, may be considered in a great degree as private property, and it may therefore be presumed that the fishery is conducted to the greatest possible extent and advantage From the extremity of the Highlands, and from the Orkney and Shetland islands, these fish are sent up to the London market, as before mentioned, in ice, and when the season is at its height, and the catch is more than can be taken off hand fresh, they are then salted, pickled, or dried, for winter consumption at home, and for the foreign markets. Perhaps the fishery of the Tweed is the first in point of the quantity caught, which is sometimes quite astonishing, several hundreds being taken at a single draught of the net. It is here where the kitted salmon is principally prepared for the London market, being first boiled and then pickled with vinegar.

General Survey of the British Fisheries.

The annual value of the Scotch and English fisheries, and the number of persons and craft employed on them, are but vaguely stated in the statistical reports of the several maritime counties of Great Britain; and in some of them the subject, important as it certainly must be considered in our economical system, and as connected intimately with the subsistence and employment of the labouring poor, is altogether omitted. This defect is more particularly to be regretted at this moment, when inquiries are anxiously making, not only how to employ a superabundant population, but to ascertain to what extent the powers of the country are capable of supplying the means for its subsistence. Indeed, we conceive that a statistical survey of the British fisheries, as far as it could be made out, would afford a most valuable document in aid of a more complete investigation of that branch of political economy which relates to the employment and the feeding of the people. The following brief account must, therefore, be considered as very imperfect. It is to be understood that the returns of the herring-fishery, as given in the preceding Table, are not taken into the account.

Sutherland.—The waters in which the salmon-fishery is chiefly carried on in this county, are those of Naver, Helmsdale, and Brora, and the rent of these fisheries is about L.1700 a year; the produce L.6800. In one year (from December to March inclusive) were caught between Bighouse Bay, on the north coast, to Rou-stoir in Assynt, on the west coast, 30,000 lobsters, which at threepence a piece, the price paid to the fishermen, amounted to L.375. They were carried in smacks to the London market, where, at that season of the year, their value was estimated at L.7000. It is estimated that each of the 37 boats on the coast of Assynt might produce L.100 a-year. Three boats at Golspie are stated to make about L.150 a-year by haddocks only, which are consumed by the country people. Of the quantity of cod and ling exported no account is given, but these valuable fish are taken in great abundance on every part of the coast. Whatever opinions may exist with regard to the policy of the measures which have recently been adopted with regard to the tenantry of this county, there can be but one in considering the Marquis of Stafford as a great promoter of the fisheries, and a benefactor to all who are concerned in them

Caithness.—It is asserted, with every probability of truth, that there is no district in Europe better calculated for carrying on the fisheries, either in point of profit, variety, or extent, than Caithness. In the fresh waters of the county, and the seas by which it is surrounded, are enumerated 45 different kinds of esculent fish. Next to the herring, the cod-fishery, near Thurso, may be reckoned as the most important. Indeed, the whole coast of Wick and Latheron, and every part of the Pentland Frith, abounds with this valuable species of fish, as well as all the other kinds usually distinguished by the name of white fish. The herring-fishery, as will be seen in the preceding Table, holds a high place among the established fishing stations; and, in fact, the whole county feels the beneficial effects of an active prosecution of the fisheries, out of which has of late years risen a new town, near Wick, named Pulteney Town; and all the villages on the coast are in a progressive state of enlargement and improvement from the same source.

Ross and Cromarty.—In the report of the agriculture of these counties, by Sir George Mackenzie, are some excellent observations respecting the herring-fishery, the decline of which, previous to the late act, he ascribes to the circumstance of salt being delivered to the fishers free of duty; which made the fishermen rely on the greater part of their expences, and some part of their profits, being paid by the fraudulent practice of smuggling the salt for sale; and to such an extent was this practice carried, that it is broadly asserted, "there is not a farmer in the Highlands who uses any other than fishery salt for butter, cheese, and other provisions; there is no other salt used in private families."

The cod-fishery of Gairloch is the most productive of any on the coast of Scotland. The fishing is from January to April. The fish are small in size but rich; averaging about five pounds when cleaned for salting. They are mostly pickled, and also dried, and sent to Ireland, Liverpool, and London. The average annual produce is about 20,000 cod, taken by 20 boats, each having about 400 hooks, which number, it is stated, might easily be doubled. For the success of this fishery, those who follow it are greatly indebted to the bounty and judicious assistance of Sir Hector Mackenzie.

Nairn and Moray.—The principal fishery of this part of North Britain is that for salmon, chiefly in the rivers Nairn, Findhorn, and Spey, the whole of which, supposed to amount yearly to about L.25,000, is exported to the London market in smacks of 80 or 100 tons burden, packed to the number of three or five in a box with pounded ice. These smacks keep the sea in all kinds of weather, and generally reach their destination from the fifth to the ninth day. When salmon begins to be too plentiful in the market, it is then boiled and sent up in kits. The price is so high where caught, that salmon is considered as a luxury, and is exhibited only at a feast.

Aberdeen.—The salmon-fishery is the most considerable in this county, and most productive on the Dee and the Don. The usual practice, formerly, was to salt the fish, pack them in barrels of about four hundred weight each, and export them to the south of Europe. In 1798, the quantity caught on the Dee was equal to 1890¼ of these barrels, and on the Don 1667 barrels. At present they are sent up fresh to the London market; and it is stated, that the price, since 1768, has increased in a five-fold proportion, and that not more than one pound of salmon is consumed in the county for forty that are exported. The fishings on the Ugie, the Ythan, and coast near these rivers, vary from 200 to 600 barrels.

The ordinary sea-fishing for haddocks, cod, ling, skate, turbot, halibut, &c. is stated to employ a number of fishermen, who carry on their occupation chiefly in small creeks, and that it brings in yearly from L.15,000 to L.30,000, the greater part of which is consumed within the county; excepting about 500 barrels of cod, and a considerable quantity of ling exported from Peterhead; from which place also, and Aberdeen, the Greenland whale fishery has been carried on with great success.

The whole of the fisheries connected with the county yield from L.80,000 to L.100,000 annually.

Kincardine.—The sea-fishing, or white-fishery, as it is usually called, is stated to have greatly fallen off in this county. In upwards of thirty miles of sea-coast, the annual value of the white-fish caught, and chiefly consumed in the county, does not exceed L.6000, giving employment to about 303 fishermen or 200 families, or 900 souls. The number of boats is about 43, and of yawls 27.

The salmon-fishery is of more importance; that in the North Esk is farmed at upwards of L.2100 a-year. This, however, is the principal fishery; all the other waters in the county not producing a rental of more than L.300 a-year.

The Lothians.—Except a limited herring-fishery at Dunbar, and a local fishery for the county supply of the neighbouring towns, the only other fishery deserving of notice, as a branch of trade in East Lothian, is the oyster-fishery at Prestoupans. From this place have been sent to fatten, in bays near the mouths of the Thames and Medway, thirty cargoes in one season, each cargo consisting of 320 barrels, and each barrel containing 1200 saleable oysters, which brought in about L.2500; the quantity consumed near the spot, and in Edinburgh, brought somewhat more, and this branch of trade gave occasional employment to about 40 boats.

In that part of the Frith of Forth which washes the coast of West Lothian, besides a herring-fishery, on a limited scale, a scanty supply of cod, haddocks, whitings, skate, flounders, crabs, lobsters, and oysters are taken for the use of the neighbouring towns.

Dumfries.—The only fishery of any importance in this county, is the salmon-fishery in the Solway Frith, and the rivers, chiefly the Annan, falling into it, the rents of which do not exceed L.1400 a year, and are supposed to be too high; the fishing having greatly decreased in consequence of the destructive engines made use of by the renters. It is stated by one gentleman, that the number of salmon taken is not equal to one in one hundred some forty years ago.

Inverness.—The salmon-fisheries in the lochs and rivers of this county are those of most importance, and let for about L.3000 a year. Those on Loch Beauly and Loch Ness are the most valuable. A singular method of taking salmon is described near Invermoriston, where the river flows in a narrow chasm between two projecting rocks: "The fisherman seats himself on a cleft of this rock, right over the cascade, with a spear in his hand, which has a line fixed to the upper end of the shaft, similar to the practice of fishing for whales with harpoons. Whenever the salmon makes a spring to gain the ascent over the cataract, the spearman strikes the fish and lets the shaft go, holding only by the line until the fish has exhausted his strength; then the spear and fish are thrown ashore by the stream, and taken out at the lower side of the pool."

Argyle.—The whole of this county is so intersected with sounds, straits, lochs, and rivers, that the fisheries might be carried on within them to almost any extent; and fishing is accordingly the occupation of a great number of its inhabitants; there being in the whole about 1500 fishing-boats employed, of which Lochfine alone employs 600; and the value of the fish caught is stated to be from L.40,000 to L.50,000 annually.

The Hebrides.—The following is the whole account of the fisheries of these numerous islands contained in the *Agricultural Survey*. "These" (the fisheries), says Mr Macdonald, "do not belong to an agricultural survey; but they are of very essential importance to the Hebrides, and therefore merit notice in this place. They bring into those isles L.200,000 a year, at an expence perhaps of L.120,000; that is, they yield a clear profit in money and sustenance of L.80,000 to the natives. They occupy, together with the kelp manufacture, 2502 boats and vessels of every description, and for some months in the year 10,500 sailors. The fencible men, or those between the age of sixteen and twenty, being one-fourth of the population, are 22,762; so that nearly one half of the effective male population is connected with the fishery. The principal fishing ports are Rothesay in Bute, Stornoway in Lewis, Tobermory in Mull, and Portnahaven in Islay; but the districts of Harris, Barray, South Uist, Skye, and various other islands, fit out a number of boats annually, or supply the Clyde busses with excellent mariners and fishermen."

English Fisheries.

Berwick.—London, it has been already observed, receives a very considerable portion of its fresh salmon from the fishery on the Tweed, that on the English side of the river alone giving employment to 70 small boats and about 300 fishermen. The value is not mentioned, but it is stated, in the *Survey of Durham*, that the rents amount to L.15,766 annually, and that so far back as 1807, the number of boxes sent to London was 8115, of eight stone each, or 67,560 stone, which, at 16s. a stone, is L.54,000, besides what is killed for exportation, and what is sold fresh in the neighbourhood. The salmon, as they are caught, are packed in ice and sent away in the vessels well known under the name of Berwick smacks. Formerly it was all pickled and kitted, after being boiled, and sent to London under the name of Newcastle salmon; but the present mode has so raised the value of the fish, as nearly to have banished this article of food from the inhabitants in the environs of the fishery, except as an expensive luxury. Within memory, salted salmon formed a material article of economy in all the farm houses of the vale of Tweed, insomuch that in-door servants often bargained that they should not be obliged to take more than two weekly meals of salmon. It could then be bought fresh at 2s. the stone, of nineteen pounds weight; it is now never below 12s. often 30s. and sometimes two guineas.

The coast fishery is not of very material importance. It gives employment to upwards of 100 fishermen, at eight small fishing stations, with about 20 boats. The fish-carriers, under the name of *cadgers*, purchase and distribute the white fish, codlings, haddock, whitings, skate, holibut, and flounders, with a very few turbot, into the inland country, and often as far as Edinburgh. Cod and ling are generally contracted for, by the season, at a fixed price, by the fish-curers, who either salt and dry them, or barrel them, as the weather may serve. The fisheries on the coasts of Cumberland, Northumberland, Yorkshire, and Lancashire, are not once adverted to in the agricultural surveys of these counties.

Durham.—The salmon-fisheries in the Tyne, the Wear, and the Tees, are stated to have declined very much of late years, in consequence, it is supposed, of throwing dams across them, which prevent the fish from getting up the rivers to spawn.

Lincolnshire.—On the coast of this county the fisheries appear to be almost wholly neglected. There is a little fish, however, in the east and west fens, called a Stickleback so numerous, that a man has made 4s. a day by selling them at a halfpenny a bushel. They also come from the sea into Boston haven, where they are purchased for manure, being more powerful than any other kind known, even that of the whale refuse. It is almost unnecessary to state that, in this fenny county, pike, carp, perch, and tench, are most abundant.

Norfolk.—The Norfolk surveys take little notice of the fisheries. It appears that the sticklebacks are caught in immense quantities in the Lynn river, about once in seven years, and are purchased for manure at the rate of sixpence or eightpence a bushel. It is mentioned, however, in Kent's *Norfolk*, that herrings to the amount of L.50,000 are annually exported, but that fish, for the use of the inhabitants, are neither regularly supplied, nor cheap; that the best fish are lobsters, soles, and cod; that the whitings are small, and the oysters very large.

Suffolk.—Besides the herring fishery carried on from Lowestoff, by forty or fifty boats of 40 tons each, the mackerel fishery is pursued during the season, with great vigour. The value of this fish, caught in the course of six weeks, is stated to exceed L.10,000, independent of the usual kinds of white-fish for the supply of the neighbourhood and the London market, the total value of the fishings being not less than L.30,000 a year. Most of the herrings caught here are dried and sent to the ports of the Mediterranean

Essex.—The oyster-fishery is of all others the most important to this county. The principal station of the dredging-boats is at Mersea in Blackwater, which, with the Crouch and the Coln, are the most extensive breeding rivers in Essex. The oysters are brought from the coasts of Hampshire, Dorset, and other maritime counties, even as far as Scotland, and laid in the beds or *layings* in the creeks adjoining those rivers. The number of vessels immediately employed in the dredging for oysters are about 200, from 12 to 40 or 50 tons burden each, employing from 400 to 500 men and boys. The quantity of oysters bred and taken in this county and consumed annually, mostly in London, is supposed to amount to 14,000 or 15,000 bushels. All the other fisheries connected with this part of the coast are stated to employ a capital supposed to amount from L.60,000 to L.80,000.

Middlesex.—This county, having no fishery of its own, but the very trifling one afforded by the Thames, is infinitely the greatest consumer of fish, and demands a larger supply than all the rest of the empire together. By a return of the cargoes of fish brought by water to the Billingsgate market, it appears that, on an average of six years ending 1785, the number of cargoes amounted to 1560, and of four years, ending with 1803, the average was 2428; the average tonnage being about 50 and the general average of fish in each about 40 tons, which will give nearly 100,000 tons of fish. Supposing the quantity brought by land carriage to be one-fifth of the other, the whole weight of fish brought to the London market, would amount to the enormous quantity of 120,000 tons a-year, which, supposing the capital and its environs to contain 1,200,000 inhabitants, would allow 200 pounds of fish annually to each individual, and, of course, a very considerable quantity must be dried or salted fish for exportation, if the returns be at all correct.

Kent, Sussex, Hampshire, and Dorset.—In the *Agricultural Surveys* of these counties, little notice is taken of the fisheries; in the first they are not mentioned. In Sussex, the produce of the ponds in carp, tench, and perch only are noticed, and even these, it would seem, are monopolized by a London fish-dealer. In the rivers of Hampshire the salmon-fishery is carried on, but to no great extent. The little town of Hamble, on the shore of the Southampton water, has about twenty sail of well and other boats constantly employed in fishing, and go as far as the Scilly islands and the Land's End for lobsters, crabs, and craw-fish in the season. In the winter they dredge for oysters, and for about a month catch vast quantities of herrings round the Isle of Wight, whose waters also afford employment in the whitings, plaice, prawns, shrimps, lobsters, and crabs, with which they abound. Southampton market is generally well supplied with all kinds of fish, and Portsmouth pretty well, but not equally so with the former place The town of Poole in Dorset is deeply engaged in the Newfoundland fishery. Along the sea coast of all these counties, the mackerel-fishery during the season, and the taking of the various kinds of white-fish, especially soles and whitings for the London market, and the supply of the neighbouring towns, occupy a very considerable portion of the inhabitants of the former place.

Devonshire.—The supply of salmon in the waters of Devon, was formerly so abundant, that here too the farmers, in hiring their servants, found it necessary to stipulate that they were not to eat salmon more than twice a week; but the case of late years is widely altered; the fishery having fallen off so as to be of little or no importance. This is stated to be owing to a wasteful and improvident destruction of the species, by taking the young fish on their return seaward towards the end of the year; no less than a thousand having been taken in one week at Brightley on the river Taw, where, and at Umberleigh, it has been usual for the young salmon fry, or gravellers, to be given to the pigs.

The sea-fishery is conducted with a considerable degree of activity in this county, Brixham alone having no less than 100 sail of vessels employed in the fisheries. They catch soles, whitings, flounders, gurnet, John Dories, and the red mullet in great abundance and of the finest quality, which are sent off to London, Bath, and Bristol, also to Plymouth and Exeter, and the neighbouring towns; and when, in the summer season, the catch is greater than can be disposed of, the fish are well cleaned, salted, and dried in the sun; thus prepared, they take the name of *buckhorn*, and are esteemed an excellent relish, much sought after in the navy, and also along the French coast.

Cornwall.—In addition to the different kinds of fish which are taken off the coast of Devon, Cornwall has the advantage of an annual visit of vast shoals of pilchards, equally abundant for the space they cover with the shoals of herrings. The four principal ports from which the pilchard fishery is carried on, are Fowey, Falmouth, Penzance, and St. Ives. At Polperro, which is perhaps the smallest establishment, upwards of forty boats and nearly 200 fishermen are engaged in the hook and line-fishery, and the aggregate value of the fish taken, is supposed to amount to L.5000 annually, most of which is distributed all over the country to the distance of thirty miles by men and women carriers. The markets of Exeter and Bath, Plymouth, Liskeard, Tavistock, &c. receive supplies from hence; and lobsters are delivered to the Southampton well-boats for London. The neighbouring poor are supplied almost all the year round with fresh and salted pilchards. Indeed, the multitudes which are taken of these fish are enormous on the coast of Devonshire as well as Cornwall, between the months of July and September inclusive, when the whole line of coast presents a scene of bustle and activity. The fish for foreign export and winter consumption are laid up on shore in large stacks or piles, with layers of salt between each row; here they are suffered to lie for twenty or thirty days, during which time a vast discharge of pickle mixed with blood and oil takes place, all of which is carefully caught in pits and preserved for manure, which is eagerly purchased by the farmer and carried away in casks. It is said that every pilchard will dress and richly manure one square foot of ground. The fish are then carefully washed with sea water, dried and packed in hogsheads, in which state they are sent abroad. The average value of pilchards taken in one year in Cornwall is supposed to be from L.50,000 to L.60,000.

Somerset.—The salmon and herring-fisheries of Porlock, Minehead, Watchet, and other places on the shores of the Bristol Channel, are stated to have been carried on to a considerable extent, since the duty on salt used for curing fish for home consumption has been removed; and the increase of the latter fishery has been the means, not only of furnishing employ during the winter for the seamen who are engaged in the lime, stone, and culm trade during the summer, but of providing a cheap and wholesome food for the labouring class of inhabitants.

Fisheries of Wales.

The great extent of coast, washed by the sea, and the numerous fine streams and navigable rivers by which it is intersected, give to the principality of Wales the advantages of a fishery little if at all inferior to those in Scotland. In South Wales, Milford Haven, and its tributary streams, the Towy, and its branches, the Laughor, the Teivy, and the Dovy, all navigable, abound with the finest salmon, sewin, trout, samlets, &c. and the same kind of fish are equally plentiful in the twenty-two inferior streams, which fall into the sea on the coasts of the four maritime counties of Glamorgan, Caermarthen, Pembroke, and Cardigan. The value of the salmon sent to Bath and Bristol from Monmouth alone, the produce of the Wye, Usk, and Rumney, is said to exceed L.4000 annually, exclusive of what is consumed in the county. The sea affords them annual shoals of herrings, which, with potatoes, is one of the chief articles of sustenance for the poor. They first appear in the bay of Cardigan towards the middle of September, just as the harvest is finished. The other sea fish are cod, haddocks, whitings, skate, ray, turbot, plaice, flounders, soles, mullets, gurnards, mackerel, dories, shad, &c. Shell-fish of all kinds are most abundant, and in various parts of Milford Haven are inexhaustible beds of oysters of superior excellence. Those of Tenby and other parts of the coast are of enormous size, but of inferior quality to those taken in Milford Haven.

It is worthy of remark, that the *sewin* is a fish peculiar to South Wales, and is not found in any river east of the Wye, or north of the Teivy, but frequents all the intermediate rivers, which they visit annually about the beginning of June, and continue in season till the end of August, weighing from 1½ to 4 or 5 lbs. each. The samlet is a small fish about nine inches long, and frequents all the rivers in which salmon and trout are found; and it has been concluded, from the circumstance of a female samlet being utterly unknown, that they are the hybrid offspring of the female salmon and the male trout. As an article of food, they are excellent when fried, potted, or pickled.

In North Wales, the sea fish are of the same description as those of the southern coast; and the herring fishery in the bay of Caernarvon is, perhaps, the most flourishing in all Wales; but the badness of the roads, and the distance by sea from any great market, check the demand for fish, and discourage the people from following the occupation. A good road from Caernarvon into Shropshire, to open a direct and speedy conveyance to the heart of England, where sea-fish is scarcely known to nine-tenths of the community, would be the means of increasing the demand for this palatable and wholesome food, of which the supply, along the extensive coast of North Wales, is inexhaustible.

Irish Fisheries.

The sea-coasts of Ireland are as abundant, and perhaps more so, in every valuable species of fish, as those of Great Britain. Its numerous bays, creeks, inlets, lakes, and rivers, swarm with them. It is visited annually by vast shoals of herrings, and the banks near its shores are well stored with excellent cod, hake, and ling, equal in all respects to those caught on the banks of Newfoundland. With the westerly winds, which may be reckoned to blow for nine months in the year, the produce of these fisheries might always be sent to ready markets at Bath, Bristol, Liverpool, and other great towns on the western and southern coasts of England; yet, either from indolence, want of inclination, or, which is more probable, want of capital, and most of all from want of proper regulations, the Irish have hitherto done little more than procure from their fisheries a scanty supply for the chief towns, and the families of those who are resident near the coast. It would seem, indeed, that the Irish have not much taste for a seafaring life, few of their young men volunteering for the navy, while they go in shoals into the army; and those few who follow the occupation of fishermen are so much prejudiced in favour of their own clumsy methods of proceeding, as to resist all attempts at improvement. It is stated by Mr Whately, in his *Hints for the Improvement of the Irish Fishery*, that, when the trammel net was attempted to be introduced, by which, in a couple of hours, more fish might be taken than with their hookers in a whole night, such was the prejudice against this new mode of fishing, that the crews of the hookers, alarmed at the supposed diminution of their profit by the increased supply, combined together along the whole coast, and destroyed the trammel nets wherever they were discovered. There is, however, a species of trall not commonly made use of, which, according to the opinion of Mr Mitchell, is highly injurious to the Irish fisheries.

"The common method of fishing in this manner on the coast," says this author, "is with what they call a beam-trail, or trall, which consists of a large beam, or pole, generally between twenty and thirty feet long, headed at both ends with large flat pieces of timber, which resemble the wheels of a common cart; except that, instead of being round, like them, they are rather semicircular, or resembling a heart cut in two, lengthways. They are shod, like the wheels of a cart, with iron. To this beam the trail net or bag is fixed, and at each end ropes are fastened, by the help of which the ground is entirely swept so clean, that I have been assured a fisherman will venture to throw his knife or any other such small matter overboard, in thirty or forty fathom water, and readily take it up again; and thus the ground is swept clean for a considerable tract; at every put, as they call *it*, the boat commonly sailing a mile, or perhaps a league, before the bag and beam are hauled up.

"It has great inconveniencies; for, *1st*, It sweeps and tears away all the sea plants, moss, herring-grass, &c. which some fish feed on, making those species to seek elsewhere for food. *2dly*, It disturbs and affrights the larger kinds of fish, as cod, ling, &c. in the same manner as if pursued by larger fish of prey. And, *3dly*, which is worse than all, these beam nets, and others of the kind which are dragged along the ground, tear away, disturb, and blend up the spawn of many kinds of profitable fish, in a terrible manner: and often many hogsheads of their spawn are drawn up in the trall bags, in which may be distinctly seen several thousand embryos of young fish."

Under proper regulations, the Irish herring-fishery would no doubt equal, if not exceed, that of North Britain. At present no pains are bestowed in the salting and gutting of them. In some parts of the coast, they are thrown into holes dug in the earth, and there salted, from whence they are sent in bulk to Cork, and other places, to be put into barrels. Loch Swilly is one of the principal bays for the herring-fishery. The salmon-fisheries in the North of Ireland might be rendered very valuable. That of Coleraine is, perhaps, the most productive; five hundred to nearly a thousand fish being sometimes taken at a single draught. They are mostly pickled for exportation.

Fisheries of the Isle of Man

If the information be correct which is stated by Mr Fraser, in *A Letter to the Right Honourable Charles Abbot*, nothing can more strongly exemplify the beneficial effects arising from the free use of salt without being subject to bonds, pains, or penalties, than those derived from the privilege granted by Parliament to the inhabitants of the Isle of Man, to import salt from England duty free, not only for curing fish, but for all other domestic purposes. "In the year 1784," says Mr Fraser, "I had the honour to be appointed by the Treasury to make an inquiry into the state of the revenue and fisheries of that island. I found that, at that period, without bounties on their boats, or the tonnage of their fishing smacks, or any premiums other than the free use of salt, they carried on a most extensive fishery, which employed 2500 seamen. In the absence of the herrings, the fishermen supplied the consumption of the island in great abundance with white fish; the agriculture was greatly increased, and the population consisted of 30,000 souls, having nearly doubled the number of its inhabitants in fifteen years." It further appears, from the *Report of the Committee of the House of Commons for the Fisheries in 1798*, that their boats had increased, both in number and size; that from a burden of ten or twelve tons, they had now advanced from sixteen to twenty-two tons, of which the number exceeded 350, each employing seven or eight men; that they had, besides, from forty to fifty fishing smacks, from twenty to forty tons each, the whole employing upwards of 3000 seamen, which were then equal to the number of men and boys employed in the whole of the buss fishery of Scotland, supported by bounties to the extent of L.20,000 a-year.

Foreign Fisheries

The fish which we have said to be next of importance to the herring in point of value, is perhaps not inferior to it in point of numbers. Like it, too, the cod is supposed to be migratory, though confined chiefly within the limits of 44° or 45°, and 68° or 70° of latitude, and is found generally on banks covered with a considerable depth of water, and the deeper the water the better is the quality of the fish. It is for this reason that the great Banks of Newfoundland, those near Ireland, the coast of Norway, the Orkney, and the Shetland Islands, and other banks in the North Sea, the principal of which are the Wellbank, the Doggerbank, and the Broad-forties, are resorted to as the most favourable spots for the cod-fishery.

Newfoundland Fisheries

Of all others, however, the Banks of Newfoundland are most esteemed, and are, in consequence, the general fishing grounds of all European nations, more especially the English and French. Formerly the Portuguese were the great fishers on those banks, and had their establishments on shore, but their fishery, like their commerce, fell with the fall of their naval power; and they are now content to buy their fish in their own ports, brought thither by ships belonging to foreigners. The Dutch have also for many years abandoned a fishery which they found less profitable than that nearer home. Indeed, so jealous were we once of the Dutch fishing on the Banks of Newfoundland, that Sir William Monson, in his treatise of the fishery, cautions the government to beware of letting them in; "for," says he, "they are like a serpent that never stings so deadly as when it bites without hissing." The French by the treaty of 1763 with Great Britain, were limited in their fisheries to the neighbourhood of the small islands of St Pierre and Miquelon; and the Spaniards, by the same treaty, agreed to abandon the Newfoundland fisheries altogether.

Since that time, however, a more formidable rival to the British fishery has started up in that of the Americans, who, of late years, have prosecuted the cod-fishery with great vigour, and with advantages which the English, with the possession of Newfoundland, are unable to command; owing, in a great degree, to the regulations by which this ancient possession of the British empire has till very lately been governed.

In a pamphlet, entitled *Considerations on the Expediency of Adopting Certain Measures for the Encouragement or Extension of the Newfoundland Fishery*, supposed to have been written by the Secretary of Lord Gambier, when Governor of that island, it is stated, that, in the year 1805, the number of vessels employed in the American fishery amounted to about 1500, carrying about 10,000 men, and that the quantity of fish caught by them amounted to 800,000 or 900,000 quintals, while the whole produce of the British Newfoundland fishery of that year did not exceed 500,000 quintals; and that the number of vessels and men employed did not amount to one-half of that employed by the Americans.

The causes assigned for this increasing success on the one hand, and falling off on the other, are as follow: The New England fishery, in all its branches, is carried on by shares, each man having a proportion of his own catch, and few or none being hired as servants on wages. By this mode the fisherman's interest being proportioned to his industry, he is actuated to labour by the most powerful incentive. The American fishermen are remarkable for their activity and enterprise, and not less so for their sobriety and frugality; and, in order to be as independent as possible on the owner of the vessel, each fisherman victuals himself, and the crew take it in turns to manage and cater for the rest. It is hardly necessary to add, that men, provisions, and every other article of outfit, are procured upon much better terms in the United States than in Great Britain. But the English fishermen must not only lay in a large stock of provisions out and home at a dear rate, but must also carry out with them a number of persons to assist in the fishery, who, consequently, eat the bread of idleness on the passage out and home; for the laws by which the colony was held were such as almost to forbid residency, and those who did reside had no power of internal legislation; they were restrained from erecting the necessary dwellings for themselves and their servants; they were prohibited from enclosing and cultivating the land, beyond the planting of a few potatoes; and from the importation of provisions from the United States, except only on such conditions as were not calculated to afford the residents much relief. "From a system," says the author of the pamphlet above mentioned, "the first object of which is to withhold that principle of internal legislation, which is acknowledged to be indispensable to the good government of every community, which restrains the building of comfortable dwellings in a climate exposed to the most inclement winter, which prohibits the cultivation of the soil for food, and restricts the importation of it from the only market to which the inhabitants have the power to go,—from such a system it is not surprising that the inhabitants of Newfoundland are not able to maintain a competition against the American fishermen."

During the late war, however, when France was completely driven out of her fisheries in the Gulf of St Lawrence, and the islands of St Pierre and Miquelon, the British and the resident fisheries about equalled, in the amount of fish taken, that of the Americans in the same quarter; who employed, in the year 1812, about 1500 vessels carrying each ten men, making, in the aggregate, the enormous number of 15,000 men employed in this branch of trade alone. The English merchants of London and Poole complain, and not without apparent good grounds, of the extraordinary privileges which America enjoyed at Newfoundland; in being permitted to cure and dry her fish on shore; which privileges, granted no doubt on an expectation that such a liberal proceeding would have paved the way to a reciprocal friendly conduct on her part, became a source of gross abuses and of unwarrantable claims. By the assembling together of numerous fleets, they interrupted the occupations of our residents; they destroyed their nets, enticed away their servants, smuggled into the colony coffee, tea, spirits, tobacco, India goods, and other articles of contraband, undersold the inhabitants in stores and provisions, and added insulting and abusive language to their manifold injuries.

Since the conclusion of the war, the United States have been re-admitted, by a convention, to all their former privileges of curing and drying their fish on the unsettled bays, harbours, and creeks of Nova Scotia, Labrador, and Newfoundland; but under certain modifications, which it is hoped will prevent those abuses which existed in a flagrant degree previous to the war. The Great Bank, from its distance from the shores of Newfoundland, is of course free to all the world; but the fishery can only be successfully carried on by a constant and uninterrupted communication with the shore, and the nearer to the shore that the fish are taken, the more advantageous is it to the fishermen. The Americans, being restrained foom fishing within certain limits, and having the privilege of curing and drying their fish only at certain spots on the shore, labour under a comparative disadvantage with us in this respect, which serves to balance the advantage they possess over us in others. Under this convention, the fishermen of the United States are at liberty to take fish, in common with the subjects of his Britannic Majesty, on that part of the southern coast of Newfoundland, which extends from Cape Ray to the Ramean Islands, from Cape Ray to the Quirpon Islands, on the shores of the Magdalen Islands, and also on the coasts, bays, harbours, and creeks, from Mount Joly, on the southern coast of Labrador, to and through the strait of Bellisle, and thence northerly indefinitely along the coast; and they are at liberty, also, to dry and cure fish in any of the unsettled bays, harbours, and creeks of the southern part of the coast of Newfoundland, and of the coast of Labrador; but so soon as the same, or any portion thereof, shall be *settled*, they are no longer at liberty to dry and cure fish at such portion, without a previous agreement with the inhabitants or proprietors; and, in consideration of these privileges, the United States renounce, on their part, any liberty heretofore enjoyed or claimed by their subjects, to take, dry, or cure fish, on or within *three marine miles* of any of the coasts, bays, creeks, or harbours of his Britannic Majesty's dominions in America, not included within the above-mentioned limits; but may be admitted to such bays and harbours, for the purpose of wooding, watering, or repairing damages only. The merchants of Poole, and others concerned in the fishery, complain of this treaty, but it appears to be well calculated to prevent those disputes and abuses which before existed, and which would probably have interrupted the harmony so desirable to be preserved between the two nations.

The importance of the fisheries on the Banks of Newfoundland, on the coast of Labrador, in the Gulf of St Lawrence, and the neighbouring islands, may be conceived, from a memorial of the committee of merchants trading to Newfoundland, addressed, in 1814, to Lord Liverpool; in which it is stated, that the catch of the French was generally estimated, at the least, at 500,000 quintals, that the Americans had reached, in 1811, nearly 1,000,000 quintals, besides fish-oil and other articles, the produce of the sea, and that the English fishery, during the American war, had increased to a degree equal to the most sanguine expectations; the export of dried cod alone, for the year 1813, having amounted to 946,102 quintals, which exceeded the shipment of the preceding year by nearly 300,000 quintals, or one-third of the catch of the whole fishery, with a proportionate increase in cod oil, seal-skins, seal-oil, salmon, &c. amounting in value to above L.1,500,000 sterling, employing in its transport to different markets at least 75,000 tons of British shipping, and 5000 seamen, independent of the persons actually employed in catching and curing the fish, and returning to England upwards of L.2,000,000 sterling.

These advantages, however, can hardly be supposed to continue, since the re-admission of the French and the Americans, both of whom, it is to be feared, will be able to undersell our fishermen in the foreign markets; the former from a considerable bounty being given by government on the fish caught and cured on the Banks of Newfoundland; and the latter from their nearness to the fishing grounds, and cheapness of the outfit. It has, indeed, been questioned by political economists, whether it would not be greatly advantageous to the national interests, if the capital employed in the distant possession of Newfoundland, and the fisheries contiguous to it, were engaged wholly in the fishery on the banks of our own seas, and those of Iceland and the coast of Norway, which are so much nearer home. Newfoundland, however, in spite of all the restrictions imposed upon it, has risen into a colony of too much importance to be abandoned; and its growing prosperity depends so much, it may be said indeed solely, on the fishery, that the residents, with the assistance of America, will always be able to carry it on independent of England. Much of late has, in fact, been done to better the condition of the colonists, and more will be required. Among other things, a resident-governor has been appointed, so that the inhabitants are not left for a great portion of the year, as heretofore, to administer justice among themselves, which was usually done in his absence by a surrogate, with a salary of L.60 a-year, and magistrates, whose occupations are in some way or other connected with the fishery.

The nature, and the value of the exports from Newfoundland, will be seen from the following Table:

Estimate of the Value of the Exports from Newfoundland between the 11th of October 1801, and the 10th of October 1802; distinguishing the Countries to which they were sent, and the Remittances proceeding therefrom to Great Britain.

				s.		L.	s.	d.		Remitted to the United Kingdom, either directly, or through Foreign Europe. L.	s.

But the following statement, taken from official documents, as the returns of the two years, ending the 10th October 1814 and 1815, will show the advanced and advancing state of the fisheries of Newfoundland, and of the colony.

In 1814.		In 1815.		Difference in one year.
				Increase.
1. Number of fishing ships, European and island bankers, ships from Nova Scotia, &c. the West India and stationary vessels, . . .	892	Number of the same description, . .	1,036	144
2. Burthen of the above mentioned ships, .	107,998 tons	Of the same, .	127,582	19,584
3. Number of men belonging to them, . .	6,966	Number of the same,	7,981	1,015
4. Number of boats kept by the fishing ships, bye-boat men and inhabitants, . . .	3,241	Number of the same,	3,518	277
5. Number of men employed in the fishery and trade in ships and boats, and as shoremen, .	19,295	Number of the same,	22,167	2,872
6. Quintals of fish caught and cured by the fishing-ships, bankers, and boats, . .	865,132	The same, .	866,580	1,448
7. Exported to Spain, Portugal, and Italy, British Europe, the West Indies, British America, and the Brazils, ...	947,811	The same, .	1,180,661	232,850
8. Tierces of salmon cured and sent to British and foreign markets, ...	3,425	The same, .	3,752	327
9. Tuns of train oil made by the fishing ships,	4,126	The same, .	4,298	172
10. The number of seal skins taken, . .	110,275	The same,	121,182	11,007
11. Tuns of seal oil made, ...	1,263	The same, .	1,397	134

The price of cod fish is, *per* quintal, from 15s. to 25s.; of salmon, from 65s. to 80s. the tierce; of train oil, from L.26 to L.34 the tun, and seal oil generally about L.36 the tun. In 1814 the number of passengers that went over from England, Ireland, and Jersey, amounted to 2800; in 1815, they were 6735. In 1814, the population of residents amounted to 35,952; in 1815, to 40,568. In 1814, the summer inhabitants were 45,718; in 1815, they were 55,284. The number of houses on the whole island was about 5000, and the number of acres under cultivation about 6000.

Northern Whale-Fishery.

If we are to credit the information which Alfred is said to have received from Octer, the Norwegians were engaged in the whale-fishery so early as the year 890. The story, however, is not very probable. The first people known to carry it on as a regular occupation were the Biscayans, who, when the English first embarked in this fishery, towards the end of the sixteenth or beginning of the seventeenth century, were always engaged as part of the crew. It continued to be carried on by the Russian and the East India Company for some years, but with no great success; sufficient, however, to induce the Dutch to attempt it. After them came the Danes, the Hamburghers, and the French, all of whom were finally driven out, or nearly so, by the Dutch. At this time the whales were so plentiful in all the bays of Spitzbergen, that the practice then was to boil the oil on shore; but when, in process of time, these large fish became more scarce, or were scared from the shore, the fishery was carried on at a distance from the land, when it was found necessary to bring home the solid blubber in casks. This circumstance was a farther discouragement to the English merchants, who, for more than a century, relinquished the whale-fishery altogether. The South Sea Company, however, revived it in the early part of the eighteenth century, when Parliament granted a bounty of 20s. *per* ton on all British ships of 200 tons and upwards, which was afterwards increased to 40s. *per* ton. This, however, by 26th Geo. III was again reduced to 30s., but several encouragements were added for the prosecution of the whale-fishery by able and expert seamen. The harpooners, the line-managers, and the boat-steerers, were not only protected from impress during the voyage, but were allowed to engage in the coal and coasting trade unmolested in the winter months, with other privileges granted by that and subsequent acts.

The decline of the Dutch whale-fishery kept pace with the decline of their herring-fishery; and from the same cause, the decline of their maritime power, which had reciprocally supported each other. The English now began to carry on the fishery with great vigour on both sides of Greenland, so as to make it an object of great national importance, both as a nursery for excellent seamen, and as a source of public wealth. On the termination of the late war, the owners of ships employed in the northern whale-fishery, alarmed at the apprehension of the Dutch and French reviving the fishery, but more so at the opening of the ports on the continent, put forth a statement of the amount and extent of the fishery, from which it would appear that 7500 men and boys are employed in it as sailors; that, by act of Parliament, the owners are required to take six apprentices for each ship of 300 tons, by which about 900 youths are constantly training for the future service of the country, and that about 200 of them complete the term of their servitude every year, when, such as are not boat-steerers, harpooners, or line-managers, become liable to serve in the navy; that not less than 300 men are also taken annually from employments on land, or from the river trade, most of whom, after two years, are competent to serve in his Majesty's navy; whom, with the apprentices and unprotected seamen employed, make a total of 4000 effective men subject to impressment.

It is further stated by the owners, that at the termination of the war, no less than 148 valuable ships, comprising 50,000 tons, and engaging a capital of L.2,000,000, were employed in the Greenland and Davis' Straits fishery; that the provisions for the voyage amount to about L.600 for each ship, forming a total of L.90,000, wholly furnished from our own markets, affording encouragement to agriculture, as well as to the various descriptions of tradesmen through whose hands the provisions are supplied; that the whole produce, therefore, of the fishery may be considered as gain to the country.

As, however, foreign ships may be sent to the fishery on more moderate terms than the English can supply theirs, and as the King of the Netherlands has offered considerable bounties to ships proceeding to the northern fisheries, all hope appears to be cut off, that Englishmen will ever be again permitted to contribute to the supply of foreign markets with whale oil, but must look to the consumption of Great Britain alone in future. It is therefore suggested by the ship-owners, as some relief, that the enormous quantity of foreign rape-seed, which has recently been imported into this country, nearly duty free, should be checked; and that, by laying a sufficient duty on the importation of this article, the protection of government would be beneficially extended at once to the encouragement of the British agriculturist, and the relief of the Greenland trader. No reasonable objection, it is stated, can be made to such a measure, unless from a mistaken apprehension with regard to its effects on the price of woollen cloths; which is so inconsiderable, that a duty of L.12 *per* last on foreign rape-seed would not occasion an advance of more than about one farthing and a half *per* yard on narrow cloths; and that, in fine cloths, Gallipol oil alone is used. This appears to be reasonable enough; but the owners of the whale-fishing ships had another and a more formidable rival in the market in the lighting of the streets of London and other great towns with Gas. It was stated, that for every three parishes in the metropolis thus lighted, five whole ships would be thrown out of employ; and that if all the parishes in London, Westminster, and Southwark, should be so lighted, it must entirely put an end to a trade which employs 10,000 seamen, 2000 apprentices, and 2000 landsmen, training constantly to the sea, and which affords occupation to 100,000 individuals. The Gas Company say, on the other hand, that the expenditure of coal will amply compensate, in a national point of view, for any loss the Greenland trade may sustain, by the additional quantity of shipping employed in bringing the coal to the metropolis. This, however, is an exaggerated statement; but as whale-oil is now employed for so many more purposes than formerly, and even in the manufacture of gas, the lighting of the streets, even if general, will probably not injure the fishery to any great extent; though the lighting of shops and private houses, should the practice become general, must seriously injure the South Sea fishery, as sperm was very commonly used for domestic purposes.

The state of the Northern Whale-Fishery will be seen from the following account of the number of fish and produce of oil, brought by the ships of the several ports of Great Britain from the Greenland and Davis' Straits Fishery, in the year 1814:

Ships.		Fish.	Oil.
58	Hull,	697	7326
20	London,	367	2981
1	Lynn,	25	187
1	Grimsby,	7	85
8	Whitby,	172	1381
5	Newcastle,	49	628
2	Berwick,	16	178
10	Leith,	73	1021
1	Kirkaldy,	7	100
8	Dundee,	61	955
3	Montrose,	47	306
2	Liverpool,	43	437
13	Aberdeen,	178	1733
7	Peterhead,	164	1390
2	Banff,	30	245
1	Kirkwall,	10	120
1	Greenock,	35	245
143	Total,	1981	19,408

50	Men in each ship.			
7150	Number of men employed annually in the northern whale fishery.			
19,408	Tuns of oil, at L.38,	L.737,504	0	0
647	Ditto whale-bone, the produce of 1981 fish, at L.80 *per* ton,	51,760	0	0
	Total amount of the produce of the Northern Whale-Fishery, in the year 1814,	L.789,264	0	0

Southern Whale-Fishery.

The statutes of 35th Geo. III. c. 92, and 42d Geo. III. c. 18, regulate the proceedings, and prescribe the conditions on which premiums of L.100 to L.400 may be claimed by each of sixteen ships employed in this fishery. Though less important, in a national point of view, than the northern whale-fishery, the number of ships and seamen employed in it are very considerable. They are fitted out mostly from London, and amounted, in the year 1815, to 107 ships, comprising 32,100 tons, and manned with about 3210 seamen; and their return cargoes were calculated to be worth about L.1,070,000 sterling.

The returns of the two fisheries, then, will stand as under:

	Ships.	Men.	Value.
In the northern fishery,	143	7150	L.789,264
In the southern ditto,	107	3210	1,070,000
Total,	250	10,360	L.1,859,264

These statements of the productive value of the foreign British fisheries may probably approach pretty nearly to the truth; but the reports of the home fisheries are too vague to afford any thing like an accurate estimate. If we should take the 120,000 tons of fish said to be imported annually into the metropolis, at the low average rate of threepence a-pound, and allow, for the rest of the consumption in the British Empire, only one-half the quantity consumed in and exported from the capital, and half a million for the export produce of the herring and cod and ling fishery, we shall have the productive value of the whole as under:

The Greenland and South Sea fisheries,	L.1,800,000
The Newfoundland fishery, . .	1,500,000
The herring, cod, and ling ditto for exportation, ...	500,000
The consumption of London and re-exportation, . . .	3,000,000
Ditto of the rest of Great Britain.	1,500,000
	L.8,300,000

And, on a general review of the number of seamen, landmen, and boys employed in the fisheries, that is to say, *on the water*, it would not appear to be too high an estimate to reckon them at 120,000. (K.)

FLINTSHIRE, a county of North Wales. It consists of a narrow tract of land, about twenty-eight miles in length, varying considerably in its breadth, in no part exceeding ten miles. The Irish Sea partly bounds it on the north; the river Dee and a part of Cheshire on a part of the north and on the north-east side, and the county of Denbigh on the south and west sides. A portion of the county is detached from the rest by the interposition of a part of Denbighshire. It is divided into five hundreds, viz. Coleshill, Maylor, Mold, Prestatyn, and Rhyddlan. The extent in square miles is 309 or 197,760 acres. By the census of 1801, the number of inhabitants appeared to be 39,622; and by the last returns of 1811, they amounted to 48,100, or one person to four acres and a half of land. Flint, the county town, in which the election for the Member of Parliament is held, and in which the county jail stands, is a small place containing only 1433 inhabitants. The river Dee formerly washed the walls of its ancient castle, but has of late considerably receded, and it has now no means of carrying on commerce by sea, except in very small vessels; and it is necessary that those should be so constructed as to remain dry, during low water, without injury. It derives some share of prosperity from having recently become a fashionable sea-bathing place resorted to by the gentry of Cheshire, Shropshire, and some other adjoining districts. Mold, the town at which the assizes are held, has rapidly increased, owing, in some measure, to the establishment of very extensive mills for spinning cotton in its vicinity. The town, including the whole parish of which it forms a part, contains now a population of 4235 souls. The city of St Asaph is neither distinguished by its extent nor the beauty of its buildings, and contains only 1520 inhabitants. Its situation, on the side of a hill, the summit of which is crowned by the cathedral, and between the rivers Clwyd and Elwy, is very imposing, and strikes the traveller forcibly as he approaches it. Though the immediate vicinity of this city has a sterile appearance, yet the views near it in one direction over the enchanting vale of Clwyd, and in another over the diversified landscape which terminates with the ruins of the castle of Denbigh, present to the eye of those who have a taste for beautiful scenery a most delightful treat.

The diocese of St Asaph extends nearly over the whole of the county, and from several livings which are held *in commendam* by the bishop, is a very lucrative preferment. The Episcopal chair has, since the Reformation, been filled by many prelates of most distinguished character. Morgan was translated to this see in 1601, as a reward for his eminent acquirements as an oriental linguist. He was employed in translating the sacred writings into the Welsh language, as well as in a part of the English edition commonly called "Queen Elizabeth's Bible." Dr Isaac Barrow, uncle to the celebrated mathematician, was eminent for his munificence to the see, as well as for his profound learning. The pious Beveridge, for a few of his last years, was Bishop of St Asaph; and the chair has been since filled by the amiable and learned Shipley, and the powerful and energetic Horsley. The cathedral has been of late much improved and beautified by the bounty of Bishop Bagot, and the liberal contributions of the nobility and gentry of the county. It was built about the year 1480, upon a foundation of much more ancient date; it is in length, from east to west, 179 feet, and in breadth, from north to south, 108 feet. The most important place in this county, from its wealth, its population, and its continued increase, is the town of Holywell, deriving its name from the well of St Wenefrede, which, in the ages of credulity, was supposed to possess miraculous powers of healing, but has of late been applied to better purposes than nurturing such superstitions. As there are many Catholics in Flintshire, the belief in the miraculous power of this spring is not wholly extinct, nor have the pilgrimages to it altogether ceased. So late as 1805, a very zealous attempt was made to revive the credit of the Saint, and establish faith in the wonderful cures achieved by bathing in her well. A case was narrated, accompanied with certificates, and a challenge given to all who doubted of the miracle, by an appeal to facts "as stubborn things;" an appeal which, however it might confirm the faith of her votaries, had no influence beyond that narrow circle. The number of inhabitants within the town of Holywell at the census in 1811 was 6394, and they have continued to increase from that period to the present time.

The productions of Flintshire that deserve most notice are the minerals, whose preparation gives employment to a considerable portion of the population.

Flintshire.

Coals are found in abundance, chiefly near the banks of the Dee, and in other parts near the surface, and in very thick seams. The city of Chester is principally supplied with its fuel from hence, and considerable quantities were shipped for Ireland before the change in the course of the Dee, and before the coal-mines of Lancashire and Cumberland had attained their present extent. Lead is most copiously raised, from a very extensive mining tract, near Holywell, and in the same excavations is raised most excellent limestone, applicable to the purposes of agriculture as well as building, and so hard, that it will bear a high polish, and is a kind of marble. Below the limestone is found petrosilex, which is ground and becomes very valuable in the manufacture of earthenware. Calamine is found in considerabe quantities; a part is exported, but much is used within the county in the preparation of brass. The lead is divided by the miners into two classes: that called cubic, or dice ore, is generally used in glazing earthenware; the other called white, or steel-grained ore, is principally cast into pigs for distant consumption; this latter contains a portion of silver, sufficient to defray the expence of separating the metals, and several thousand ounces have been annually extracted. The workmen in the lead mines are visited with maladies that both embitter and shorten their lives.

The manufactories of this county are very considerable, and have taken that course which the natural productions have indicated. Brass is made by the mixture of copper with calamine, and formed into the different shapes to fit it for domestic and commercial purposes. Copper-works, under the Pargs-mine Company, are constructed, and produce large quantities of copper sheathing, bolts, nails, and other necessaries for naval equipment, as well as brass wire and minuter articles. The potteries are very extensive, and manufacture large quantities of the inferior kinds of earthenware, which supply the consumption of a great part of Wales, and export considerable quantities to Ireland. Besides these manufactories which the minerals have introduced, the fine stream that issues from the well of St Wenefrede has attracted the attention of cotton-spinners, who have erected a most powerful mass of machinery. They carry on the operations of carding and spinning cotton to a great extent.

The agriculture of this county is in a neglected state, and draws to it a very insufficient portion of its capital; hence few improvements have been adopted of late years. Near the banks of the Dee is some good corn land, of a clayey texture, on which, after a fallow, good wheat is grown. The meadows, in this part, produce excellent herbage, and the cows afford the best possible butter. The northern part of the county is generally a level country, and well calculated for the growth of wheat, oats, and beans. On the higher lands rye is cultivated, but those lands are very imperfectly tilled, and are nearly destitute of manure. The rich vale of Mold forms a striking contrast with the more mountainous parts of the county, and yields very good butter, corn, and meat.

The ruins of ancient edifices, and other antiquities, are numerous, and invite the attention of the antiquarian. A few years ago, whilst digging for the purpose of laying the foundation of a copper work, a Roman *hypocaust*, or hot bath, was discovered, furnished with numerous flues, covered with tiles of a red colour; a clear evidence that the county had been anciently inhabited by some persons acquainted with the luxuries of Rome.

Few counties, for the extent, contain so many gentlemen's seats as Flintshire: the most remarkable are Mostyn Hall, Sir Thomas Mostyn; Pengewern, Sir Edward [illegible] Lloyd; Boddlewyddan, Sir John Williams; R[illegible]ael Hall, Reverend Edward Hughes; Gwernhaiked, Philip Lloyd Fletcher, Esq.; Hanmer Hall, Sir Thomas Hanmer; Downing, David Pennant, Esq.; Halken, Earl Grosvenor; Adwynt, J. Roberts, Esq.; Llewenny Hall, Lord Kirkwall.

Flintshire || Florida.

FLORIDA, a district of North America, belonging to the crown of Spain, having been ceded to it by Great Britain at the peace of 1783. The history of its discovery and early establishment being narrated in the *Encyclopædia*, we confine ourselves to such notices of it as were then omitted, or as subsequent events have rendered interesting.

East Florida.

When, in 1763, Spain gave up Florida in exchange for Cuba, the British government divided it into two provinces, distinguished by the names of East and West Florida. East Florida is bounded on the north by the river St Mary, in 30° 35' north latitude, which divides it from Georgia. Its eastern boundary is the Atlantic Ocean to Cape Florida in latitude 25° 55' north, when, terminating at that point, it bends to the northward. Its western boundary is the sea in the Gulf of Mexico to the latitude 29° 30° north, from whence the river Apalachicola forms the line which separates it from West Florida, till it meets the confines of Georgia. The province, in shape, resembles a wedge, the base line towards Georgia being 160 miles; and the perpendicular line from north to south being 350 miles. As the whole province is a peninsula, it presents an extended point to the sea, and from its position, as well as its formation, is calculated, when peopled, to enjoy a considerable share of navigation; but the want of secure bays and harbours, and the dangerous bars at the mouths of its rivers, forbid any very sanguine expectations of its speedy population being realized.

Rivers.

The best navigable river on the eastern side of the province is St Mary, its northern boundary. It is navigable, however, but for a short distance. The depth of water in the bar is sufficient to admit vessels drawing 16 feet, and at spring tides vessels drawing 20 feet water may enter, and when within they are in perfect safety. In the centre of this river, Amelia Island, which belongs to Florida, commands the ascent and anchorage. A small fortress and a miserable town called Fernandina, are all that this island contains. It was for a short time occupied by a piratical banditti, who assumed to be South American republicans, and was at last seized by the United States troops, under pretence of dislodging the depredators.

The river San Juan is about half way between St Mary's and St Augustine. Its entrance is difficult, and will not admit of vessels drawing more than twelve feet water, and even with that draught, it is a very perilous navigation.

As most of the plantations, when the English possessed the province, were either on the banks of this river, or on Rio Pablo, which empties itself into it, it became the most valuable part of the province; and the town of St John's, built principally during the American war by English emigrants from the revolted states, was growing [illegible] some consideration, when its progress was checked by the peace of 1783, and the consequent removal of the British settlers to the Bahama Islands. It is now a place of little importance, and the number of its inhabitants has been fast diminishing.

City of St Augustine.

St Augustine, the capital of East Forida, is built on an inlet behind the island of St Anastasia, which forms an excellent harbour, but difficult of access. Vessels of more than ten feet draught of water cannot enter even in spring tides, and when of that draught they seldom escape without striking on the bar; the greater part of the cargo is therefore usually landed by lighters before an entrance is attempted. The entrance is defended by a fort on Anastasia Island, and by a strong fortress on the main land. This fort, St Mark's, was originally built by the Spaniards, but considerably improved and strengthened by the British. It is built of stone, has four bastions, the curtains between each one 180 feet in length, and the rampart is 20 feet in height. The buildings are very strongly constructed, they are partly casemated, and mostly bomb-proof. The city is defended by a double row of lines which stretch across the neck of land that connects it with the country; and thus, if it were worth attacking, with a sufficient garrison, it is capable of an obstinate defence. The town contained, when the Spaniards held it, about 4000 inhabitants of various descriptions, including a garrison of 400 soldiers. When, in 1769, it was ceded to Great Britain, the inhabitants, with that attachment to the mother country, its religion, and its government, which Spaniards, and their descendants, have preserved in every part of the globe, left the province, and settled either in Cuba, Hispaniola, or Louisiana. Only two families remained under the British government, and one of them in the distant woods.

Soon after possession was taken by the British, various plans were projected for settling the province. The late Mr. Denis Rolle, father of the Peer of that title, established a large plantation on the river St John. The Beresford family of Ireland attempted another establishment on the same river. The reports of the healthiness and fertility of the country attracted various settlers under the auspices of these patrons, but the projects were ultimately unsuccessful, and were finally abandoned. The Grenville family adopted a more splendid project. Under their patronage, Dr Turnbull collected numerous emigrants from the island of Minorca, and conveyed them to East Florida. They were bound to serve for a stipulated term of years, by articles signed before they left their native island. A settlement was made at the mouth of the river Musquito in latitude 29° 45', and called New Smyrna. The situation was supposed to be very favourable for the growth of silk and vines, to the culture of which the emigrants from Minorca had been accustomed. Considerable sums had been expended in this establishment, when discontent arose among the settlers, and after much altercation, they all abandoned the rising plantation, and removed to the capital. It is needless to add, that the project thus terminated ruinously. In subsequent suits in the courts of law, Dr Turnbull was unsuccessful, and the Minorquins declared to be freed from their engagements. By the failure of this great project the settlers became dispersed, and as they were mostly married, multiplied very rapidly, and thus the colony was growing in population,

When the revolutionary war took place, many royalists repaired from Carolina and Georgia to Florida, and further increased the numbers and the wealth of the province. In this condition, in 1788, it was ceded to Spain, in exchange for the Bahama Islands, which that country had recently conquered. As the colonial laws of Spain neither admit foreigners, except under certain conditions, nor allow any but Catholics to live on their transatlantic dominions, the plantations were broken up; the British inhabitants and their slaves removed to other countries, and only the Minorquins and their descendants remained to people the country, thus again become subject to the Spanish court. They are said to have increased very considerably, and now to amount to upwards of 5000 souls. Some few Spanish families have also removed to East Florida; but altogether, the population, including imported negroes, is not nearly equal to what existed when the British relinquished the settlement.

The city of St Augustine consists of three long streets parallel to the shore, a square or parade, and several streets that cross the principal ones at right angles. There are two churches, but neither of them large or highly ornamented. The state-house built by the British, now called the Cabildo, is a handsome building of stone, and displays considerable taste. The government-house is large and convenient, but built without any regular plan, and has by no means a prepossessing appearance. The abundance of orange trees which are growing in the town, and which are in constant bloom, and have green and ripe fruit on them through the whole year, give a pleasing appearance to this place. It is badly supplied with water, as all the springs are somewhat brackish.

There is no other place in East Florida that deserves even the name of a town. Matanzas, about twenty miles south of St Augustine, consists only of a few scattered plantations; and New Smyrna has, by the desertion of its Minorquin settlers, become almost without inhabitants. There are no settlements to the southward of New Smyrna, and only a few tribes of scattered Indians resort there for the chace. Occasionally, temporary habitations are constructed on the shore by people from the Bahama Islands, who repair thither to catch turtle, or to employ themselves as *wreckers*, by saving what they can from the numerous vessels that are stranded in their passage from the West Indies, through the Gulf of Florida.

On the western side of east Florida, though several considerable rivers empty themselves into the Gulf of Mexico, no settlements have been formed, except at the mouth of the River St Mark, and that, though protected by a fort, has gone to decay, and is now nearly deserted.

Climate.

The climate of East Florida is perhaps the most pleasant and salubrious of any in the globe. It is within the reach of the tropical winds, which, in the midst of summer, temper the heat, and give a daily freshness to the air. In winter frosts are scarcely known, and snow and ice, if they are occasionally experienced, disappear with the first rays of the sun. No country can be more free from fogs, and other noxious exhalations: and hence the troops quartered here, as well as the inhabitants, have experienced a portion of health and longevity scarcely known in any part of the western continent.

Soil and Productions.

The soil of East Florida on the sea shore is generally sandy, and covered with tall pine trees, without any underwood beneath them. It is, however, intermingled with swamps, filled with almost impenetrable woods of every description, and with extensive savannahs, well calculated for the cultivation of rice. The fine barrens, as they are called, yield with little labour vast quantities of turpentine, tar, and pitch. The turpentine exudes by the heat of the sun alone from the body of the trees, whose bark is pared away to admit of the action of the sun upon the woody fibres. It is collected by the slaves from small boxes cut in the tree, near the bottom, into which it runs; it is thence carried to a general reservoir, from which the casks are filled for exportation. In extracting tar, the pines are cleft into small pieces; a kiln is constructed with them on a grating of iron bars laid over a hole in the ground; by means of a gentle heat the tar is extracted, and runs into the pit. The pitch is made by a simple process: two or three red-hot cannon-balls are thrown into the pit in which the tar is deposited. A fire is by that means kindled in the mass of tar, which burns with a prodigious noise, and produces a very thick smoke. The burning is continued till the moisture in the tar is consumed or dissipated, when the fire is extinguished by laying hurdles over the pit, and covering them close with sods of turf. When the substance cools it becomes hard and shining, and requires axes to chop it out of the holes. After various experimental projects on the vine, the mulberry, and the indigo plants, the English settlers, from the year 1776 to 1783, almost confined their agricultural labours to the production of these naval articles, the prices of which had been increased during the war that raged in those years. The exports consisted then principally of the naval stores, with the addition of some peltry collected by the Indians in the interior.

Soon after 1783, the Spanish settlers, increased by recruits from the United States, and stimulated by the example of the citizens of Georgia, began to cultivate cotton. The northern part of the province was found admirably calculated for its growth; and hence attention and capital was attracted towards the banks of the river St Mary, and the boundary beyond that river, which divides it from Georgia. By the laws of Spain, her colonies can only export their productions to the northern country, and in ships of that nation; but the facilities of conveying the cotton-wool grown on the Spanish side, to the American side of the boundary, lessened this impediment to the cultivation of the valuable production best suited to the soil and climate. The navigation of the river was common to both nations, and the ships loaded with cotton from the American side of the river had their cargoes principally furnished to them from the growth of the Spanish territories. This contraband trade, which no laws could prevent, gave a great encouragement to the settlements on the northern part of the province, and it has consequently become both the most populous and the most wealthy. Attempts have been made to cultivate wheat, but hitherto without success; probably owing to the experiments having been tried on the sandy soil near the shores, and not on the clay lands on higher elevations in the interior. Maize and rice are abundant, and form the principal food of the inhabitants.

Quadrupeds.

The woods abound with troops of wild horses, which traverse the whole peninsula. They are of small size, but strong. They are easily taken and rendered tractable by the Indians, who bring them to the European establishments, and exchange them for such weapons as they want. Their value is so trifling, that a good saddle may be exchanged for twenty. Abundance of wild hogs are running over the country, especially over the islands on the sea shore, and near the borders of the lakes. They are not indigenous, but evidently of European origin, and seem to have changed their nature very little by having ceased to be domesticated. Numberless deer inhabit the woods; they are killed by the natives principally for the sake of the skin; but when any of the Indian hunters take them near the settled parts, they sell the flesh for food to the inhabitants, who can frequently, for a knife not worth in Europe sixpence, or for some other article of equally diminutive value, obtain the whole carcase of a deer.

Black bears are numerous; they are of a very small size, very timid, never attacking but flying from man. The hunting them is a diversion to the inhabitants, and their flesh is considered a great dainty. There are but few cows, and still fewer sheep, and none of either in an unreclaimed state. Goats have not been introduced.

Fish.

The sea coasts, the rivers, and the lakes, abound with every variety of fish, and they furnish food to the greater proportion of the people, especially on fast days, and in Lent, which the Minorquins, as well as the Spaniards, observe with great rigidity. The rivers and lakes swarm with alligators, who feed most voraciously on the innumerable fry of smaller fish. The abundance of these smaller fish is a most singular fact. The sea shore abounds with sharks, who, like the alligators, find a supply of food by preying on the smaller tribes, who, when pursued by those voracious monsters, and ascending the creeks to parts where they suddenly contract, so fill the water as to impede the passage of a boat. In some instances, where the contraction of the stream is very sudden and very great, those smaller fish have been seen so closely crowded as to become a mass actually filling the channel, and even rising, so wedged together, above the surface of the water.

Though the land near the shore is level, and the soil sandy, yet, on proceeding to the interior, the pines are no longer seen, the soil is richer, and mountains gradually rise. On the coast, the tuna or prickly pears form, with aloes, the sole fences; in advancing inland, the live oak, the hickory, chesnut, and walnut trees appear, and there are abundance of cabbage trees.

Birds.

The bird tribes are very extensive and numerous in both the Floridas. Wild ducks and wild geese are found in prodigious flights; wild turkeys are plentiful, of a very large size, some of them weighing more than forty pounds. There are, besides, bustards, herons, cranes, partridges, pigeons, hawks, and macaws, and many of the smaller kinds, thrushes, jays, larks, and sparrows.

There are some considerable lakes in the centre of the province; the most beautiful is that of St George. It is near the source of the river St Juan, is fifteen miles long, about ten in its mean breadth, and from fifteen to twenty feet in depth. In this lake are some islands; the largest of them is two miles broad, has a most fertile soil, and contains vestiges of an ancient Indian town of considerable extent. In the centre stands a lofty mound of earth, of a conical shape, from which a causeway is carried to the shore through groves of magnolias, oaks, palms, and orange trees. From the fragments dug up, the place is supposed to have been very populous. It was probably a station of the Apulachian Indians, whose remains show some approaches to civilization.

West Florida.

West Florida, in its productions, in its soil, and climate, so nearly resembles East Florida, that it will admit of a more brief description. It is bounded by East Florida to the eastward, by the Gulf of Mexico to the south, to the north its boundary is the 31st degree of north latitude from the Apalachicola to its western extremity, where the river Iberville separates it from Louisiana. The province is about 120 miles in length, from east to west, and from 40 to 80 in breadth; and, consequently, its longest side is towards the sea.

City of Pensacola.

Pensacola, the capital, is in 30° 20′ north latitude, and 87° 12′ west longitude from London. It is situated on the western side of Pensacola bay, which is a most excellent harbour, safe from all winds, has a good entrance, secure holding ground, in seven fathom water, and vessels drawing 20 feet water may enter it at all times. Indeed there is very little tide, the greatest rise not exceeding one foot. The entrance into the bay is defended by a fort on the Island of Rosa, and by a battery on the opposite shore. The city is delightfully placed on the sea-coast, extending a mile in length, and a quarter of a mile in breadth. It was fortified by the English, though not in a very perfect manner; but, being well garrisoned, it withstood a long siege from a numerous army under the Spanish General Galvez, in the year 1781. Owing to the principal magazine, which was supposed to be bomb-proof, having been entered by a shell, an explosion took place, by which almost the whole powder of the garrison was destroyed, and it was compelled to capitulate. The trade, whilst it was in possession of the British, was considerable; its exports amounting to about L.100,000 annually, and its imports were nearly of the same value. Besides the productions common to both Floridas, this division furnished considerable quantities of dyeing woods, and several medicinal plants, especially snakeroot and ginseng. The quantity of peltry collected by the Indians, and brought to Pensacola, was much more considerable than that which found an outlet by St Augustine, St John's, and St Mary's rivers.

When Pensacola fell into the hands of the Spaniards, and possession of it, as well as of East Floridas, was confirmed by the treaty of peace in 1783, the greater part of the inhabitants left the country, and settled either in the United States or the British Islands; and few Spanish settlers having fixed their residence in it, the town and province have, ever since the change, been in a desolate state. The expences of maintaining the governments of the two Floridas by Spain has so much exceeded the revenues, that they have required remittances from Mexico annually, to the amount of near 300,000 dollars.

Mobile.

Mobile, with the district around it, was seized by the American Government in the year 1810, and though the right to it depended on the unsettled question of boundary, it may be noticed here, with more propriety than under the article Louisiana, to which country the Americans asserted that it belongs. It was, when held by the British, a place of considerable importance, and most rapidly increasing. It is well situated for commerce, as the Alabama river and district must have all their productions pass by it to reach the ocean. Though vessels of large size cannot reach the town, yet they can anchor securely within the river seven miles below it; and it has the advantage of being connected by boat navigation with Tennesse by the rivers Alabama and Tombecbee, which are navigable 300 miles above the town. These advantages were lost to the place, whilst under the Spanish Government; it had rapidly decayed, and was rather a harbour for outlaws and contrabandists than a mercantile or agricultural colony. In 1810, when the events in Spain made it doubtful what government was to rule the peninsula, the inhabitants of Mobile showed a disposition to set up a government of their own. Folch, the Spanish commander, was unable to restrain the inhabitants, and he relinquished his power to the United States. Since that period Mobile has continued to increase, and as it is now assumed to be, and practically is a part of the States, it may, at no very distant period, become a place of considerable importance.

Indian Tribes.

The Indian tribes bordering on Florida, are the two nations of the Upper and Lower Creeks, the Aconies and the Seminoles. When, in 1781, the Spaniards conquered West and menaced East Florida, all these tribes were resolutely engaged in the English cause. They have, like the rest of the Aborigines, considerably diminished in numbers, as the more civilized population has approached nearer their villages. It is said, however, that these tribes when united can muster near two thousand warriors; but in this enumeration are included many fugitive negro-slaves from the States that have joined them. The inhabitants of the United States, in all the southern parts, from the feelings which their system of negro-slavery has created towards all that are not of the European complexion, too frequently treat the Indians with unfeeling cruelty. The State governments to the southward are all composed of individuals who are masters of slaves; even the Congress has a majority of its members masters of slaves; and the President, ever since the establishment of their constitution, has been chosen from the slave owners with but one exception. Coloured people, by such men, are scarcely considered as human beings. No sympathy is felt for their sufferings, and no redress is afforded to their complaints. They are treated with oppression, and they retaliate by barbarity. Peace can never be of long duration between such parties, and the justice of their cause can never be impartially ascertained. The opponents of the Indians, who alone have communication with them, exclusively possess the faculties of reading and writing; they alone have the power of printing their statements; and consequently of dressing them in such colours as best suit their own views.

As in the views of the United States the possession of the Floridas was important, they have never ceased to desire it since their acquisition of independence. No pretext either for exchanging or seizing these provinces presented itself till the Government of France became masters of Louisiana. Bonaparte having induced the imbecile cabinet of Spain to cede to him the province of Louisiana, and knowing the eagerness felt in America for the extension of a territory already too extensive, bargained with the United States for the province, before the treaty with Spain was completed. The Government of America paid the price for the stolen track, and thus became accomplices with him who had committed the fraud. A French Commissioner, M. Laussat, received the surrender from the Spanish Government, and instantly delivered over the province to the officers of the United States. No dispute then arose about the boundary. The Mississippi and the Iberville had been considered by the English, the Spaniards, and the French, as the line which divided Louisiana from Florida. Under this conviction, France received it from Spain, and with the same conviction it was delivered to America. When the United States had thus gained Louisiana, the desire for Florida became more intense; and on the most flimsy pretences, claims were set up to the track of country included between the Iberville and the Perdido, which the Americans asserted was a part of Louisiana. Appeals were made to the Government of France as to their understanding of the limits which they had received and transferred. The answer of France was, that they had only received the country up to the Mississippi, and that the district between that river and the Pardido had not been included in the cession made to them by Spain, but continued, as it had previously been, a part of Florida, which Spain was to retain. Though much discussion between the two Governments was carried on, from the time when Louisiana was transferred, no steps had been taken by America to enforce her claims; but when the Peninsula was overrun by the armies of France, and no government recognised by America existed there, the territory in dispute was occupied by the Americans, as we have before stated, with the concurrence of Folch, the Spanish commander at Mobile.

When the monarchy of Spain was restored, negociations on the subject were renewed. The disputed territory had been consolidated with the United States; but the remainder of the Floridas, which were in the possession of Spain, and to which not even the shadow of a claim could be urged by the Americans, continued to excite their cupidity. During a period of the war which France and Spain had carried on against England, depredations, as the Americans asserted, had been committed on their commerce, by privateers belonging to Frenchmen, who had captured their ships, and carried them into Spanish ports, where they had been condemned as legal prizes, before the consuls of France, who exercised judicial authority within the dominions of Spain. The Americans demanded from Spain, in no very decorous terms, compensations for the losses their citizens had thus sustained. The Spanish court replied, that they were no parties to the injury; that compensation, if any, was due from France; that the aggrieved Americans had, by appealing to the courts of revision in France, acquiesced in the construction put on these transactions by the Spanish court; and that the courts in Spain could take no steps to investigate the validity of the complaints, or to ascertain the quantum of injury sustained, as all the documentary evidence was in the possession of the French judicatures. The minister of Bonaparte asserted, that, in the negociations for the sale of Louisiana, a compensation had been made to America for these depredations; and that she could consequently have no claim on that account to urge either on France or Spain.

As long as Bonaparte ruled, the claims of America could gain no attention from him: and Talleyrand, who had been the minister that carried on the negociation, repelled, in the most indignant terms, every suggestion, and even intimation, that any account respecting these captures had not been finally adjusted. When Bonaparte was dethroned, and when Spain was entangled by the disputes with her colonies, America urged her claims with renewed pertinacity; and intimated that the Floridas might be ceded as a compensation, and that the losses, alleged to have been sustained by the merchants, should be adjusted by the American government. As Spain was unwilling to acquiesce in this unjust pretension, the Americans, to quicken her, affected to deliberate on the propriety of recognizing the revolted colonies of Spain as independent states, and sent Commissioners to different parts to ascertain the condition of those countries. The Spanish envoy, alarmed by these feints, was induced to yield, and to acquiesce in the unjust pretensions of America, and at length concluded a treaty ceding the Floridas. Whilst these negociations were carried on, however, Pensacola had been captured, and arrangements made for the seizure of St Augustine, by an American officer, who, having been sent to fight the Seminole Indians, had raised and officered an army, without any authority but his own, and in opposition to the laws of the United States.

It appears by the very able report of a Committee of the senate of the United States, that General Jackson was ordered by the war department, to take under his command the militia of the contiguous states, to attack and disperse the Seminoles, and, when peace was concluded, to dismiss the militia. That officer, however, raised and officered a regular army of 1800 men, but called out no militia; he was joined by Generals Gaines and M'Intosh with 1500 more, and, with this force, was soon enabled to disperse the Seminoles, whose numbers, when collected, amounted only to 800 or 900 warriors. When peace was thus gained, instead of obeying his instructions, and dismissing his troops, General Jackson advanced into the Spanish territory. The government had given orders, that, if the Indians should retire under the protection of a Spanish garrison, the American army was not to follow them, but to report it to the executive, and wait for its instructions. Jackson wrote to his government on the 26th April 1818, "that the Indian forces had been divided and scattered; cut off from all communications with those agents of foreign nations, who had deluded them to their ruin, and had not the power, if they had the will, of annoying our frontier." He adds, that, "after making all necessary arrangements for the security of the positions occupied, and detaching a force to scour the country west of the Appalochicola, I shall proceed direct to Nashville, as my presence in this country can be no longer necessary." Whilst composing this dispatch, however, the arrangements were proceeding for attacking the garrisons of Spain. His heavy artillery was moving from Mobile towards Pensacola, and the general, with 1200 men, joined it in about three weeks from that period, before that place. The opposition was trifling: it fell an easy prey, and the Spanish governor, with the troops, retired to the fortress of Barancas, about six miles distant. As its surrender was refused, an attack was made upon it, and, after a bombardment and cannonading for two days, and the loss of several lives, it was surrendered, and the garrison, agreeably to the terms of the capitulation, was transported to the Island of Cuba. The civil government of Spain was forcibly suppressed, the revenue laws abolished, and municipal and financial officers, from the Americans, were, by the authority of the general, appointed to the different ports.

The execution of two Englishmen, Arbuthnot and Ambrister, contrary to all the laws of civilized nations, however atrocious, is more an indication of the character of the commander, than of the nature of a political transaction, and may be passed over without remark. When the conquest of West Florida was thus achieved, Jackson gave orders to his second in command, General Gaines, to attack St Augustine, "to hold the garrison prisoners until he heard from the President of the United States, or transport them to Cuba, as in his judgment, under existing circumstances, he might think best." This completion of the general's designs was, however, frustrated by the prompt and decisive orders given to Gaines, to desist from the attempt. We are not now considering the weakness or the iniquity of the government of America, nor do we find it necessary here to solve the problem, to which of those causes the subsequent exculpation of Jackson is to be attributed. The influence of this conduct on Spain seemed, however, to have been effectual. Without a revenue, or the power of raising one, with a ministry constantly changing with all the caprices of the monarch, with a population governed by priests and monks, with the contempt of all Europe, and with insurrections of a formidable nature in its transatlantic dominions, the ambassador of Spain was reluctantly forced to yield to the insolent injustice of the American Republicans; who, for the sake of gaining the uncultivated provinces of Florida, have apparently renounced their intention of giving either countenance or support to the republicans of the south.

The treaty concluded by Don Luis Onis, on the part of Spain, has not been ratified by the court of Madrid, although the stipulated period for its completion is now past; and the present condition of Florida remains thus: The whole of East Florida is in the possession of Spain; Pensacola has been given back to a Spanish commander; and the country in dispute, between the Iberville and the Perdido, is in the hands of the government of the United States.

FLUENTS, OR INTEGRALS.

SECTION I. *Definitions.*—II. *General Theorems.*—III. *Rational Fluxions.*—IV. *Irrational Fluxions.* V. *Circular Fluxions.*—VI. *Logarithmic Fluxions.*—VII. *Exponential Fluxions.*—VIII. *Index of Fluxions.*

SECT. I.—*Definitions.*

THE fluents of such expressions, as are the most likely to occur in the solution of physical problems, may be very conveniently arranged in the form of a TABLE; the principal materials of which will be extracted from *Meier Hirsch's Integraltafeln.* 4. Berlin, 1810. It might have been somewhat enlarged by additional matter that may be found in the earlier publications of our countrymen *Waring* and *Landen,* which have been particularly consulted on the occasion; but Waring's improvements relate most commonly to cases so complicated, as seldom to be applicable to practical purposes; and Landen's theorems, though incomparably more distinct and better arranged than Waring's, tend rather to the investigation of some elegant analogies, than to the facilitation of actual computations. Some of these, however, will be briefly noticed, and an improvement in the mode of notation will be attempted, which, if universally adopted, would tend to save much unnecessary circumlocution in the enunciation of many general theorems.

1. The earlier letters of the alphabet, as far as q, and sometimes r, are commonly employed to denote constant quantities; the subsequent letters generally for quantities considered as variable. They are here employed as relating indifferently to quantities positive or negative, and to numbers whole or fractional; except when they are used as indices or exponents.

2. The Italic character is employed, in preference to others, for denoting quantities in general, the Roman for characteristic marks, as d for a fluxion, or differential, sin, cos, or f, ç, for sine and cosine; and hl for hyperbolic logarithm. The long Italic $\int$, however, not being otherwise used, serves very conveniently as a characteristic, to denote a fluent.

3. When the Italic letters m, n, p, q, r, or any others, are employed as indices, they are to be here understood as denoting any numbers without limitation; the Roman small letters, m, n, will be applied to whole numbers only, excluding fractions, but either positive or negative, or 0; the small Italic Capitals M, N, to positive numbers, whether whole or fractional, excluding negative numbers only; and the small Roman Capitals M, N, to positive integers only, including however 0.

4. The characteristic Σ implies the sum of a finite number of terms, derived from all the possible variations of a quantity, which is here denoted by a small letter of the Greek alphabet.

5. A comma, in an index, denotes or.

6. The fluents, indicated by the table, are to be understood as corresponding equally to any particular values of the quantities concerned; so that, in order to obtain the expression of the definite quantity required by the conditions of any problem, we must always take the difference of the two values found by substituting two values of the elementary variable quantities; and this rule being general, it supersedes the necessity of introducing a constant correction of the fluent in each particular case.

7. Particular values of fluents, limited on both sides, are distinguished by accents, $\int^{\cdot\prime}$.

SECT. II.—*General Theorems.*

1. $\int \mathrm{d}x = x$. See Sect. I. Art. 6.

2. $\int a\mathrm{d}x = ax$

3. $\int x^n \mathrm{d}x = \frac{1}{n+1}\, x^{n+1}$ Cavalleri was acquainted with the fluent of x^{N}; Wallis extended it to x^{n}; but Newton first discovered, in 1672, the general expression, as comprehending the fluxion of an irrational quantity.

Exception. In the case $n = -1$, the theorem fails, and we must substitute

$$\int \frac{\mathrm{d}x}{x} = \mathrm{hl}\, x$$

4. $\int y\mathrm{d}x = xy - \int x\mathrm{d}y$

5. $\int y\mathrm{d}z = \frac{\mathrm{d}y}{\mathrm{d}x}\int z\mathrm{d}x - \frac{\mathrm{d}^2y}{\mathrm{d}x^2}\int^{2} z\mathrm{d}x^2 + \frac{\mathrm{d}^3y}{\mathrm{d}x^3}\int^{3} z\mathrm{d}x^3$ $- \ldots$; dx being any constant fluxion whatever. This very elegant theorem may be applied with great convenience to all the more complicated logarithmic functions. See n. 547, 556, 570, 572. Taylor, *Meth. Incr.*

6. $\int^{\prime} \mathrm{d}y = x\frac{\mathrm{d}\mathrm{Y}}{\mathrm{d}x} + \frac{x^2}{2}\cdot\frac{\mathrm{d}^2\mathrm{Y}}{\mathrm{d}x^2} + \frac{x^3}{2.3}\cdot\frac{\mathrm{d}^3\mathrm{Y}}{\mathrm{d}x^3} + \ldots$: Y being the initial value of y, this theorem gives the increment of y corresponding to any increment of x beginning at the same time: it may be called the master key which opens a way to all the treasures of analysis. From Taylor, *Meth. Incr.*

SECT. III.—*Rational Fluxions.*

A. $x^{\mathrm{m}}(a+bx)^{-\mathrm{N}}\mathrm{d}x$

a. $\frac{x^{\mathrm{M}}\mathrm{d}x}{a+bx}$

$$7.\int\frac{x^{M}dx}{a+bx}=\frac{x^{M}}{Mb}-\frac{ax^{M-1}}{(M-1)b^2}+\frac{a^2x^{M-2}}{(M-2)b^3}-\dots$$
$$\frac{a^{M-1}x}{b^{M}}\mp\frac{a^{M}}{b^{M+1}}\,\mathrm{hl}\,(a+bx)$$

Examples.

$$8.\int\frac{dx}{a+bx}=\frac{1}{b}\,\mathrm{hl}\,(a+bx)$$

$$9.\int\frac{xdx}{a+bx}=\frac{x}{b}-\frac{a}{b^2}\,\mathrm{hl}\,(a+bx)$$

$$10.\int\frac{x^2dx}{a+bx}=\frac{x^2}{2b}-\frac{ax}{b^2}+\frac{a^2}{b^3}\,\mathrm{hl}\,(a+bx)$$

$$11.\int\frac{x^3dx}{a+bx}=\frac{x^3}{3b}-\frac{ax^2}{2b^2}+\frac{a^2x}{b^3}-\frac{a^3}{b^4}\,\mathrm{hl}\,(a+bx)$$

$$\text{b. }\frac{x^{M}dx}{(a+bx)^2}$$

$$12.\int\frac{dx}{(a+bx)^2}=-\frac{1}{b(a+bx)}$$

$$13.\int\frac{xdx}{(a+bx)^2}=\frac{a}{b^2(a+bx)}+\frac{1}{b^2}\,\mathrm{hl}\,(a+bx)$$

$$14.\int\frac{x^2dx}{(a+bx)^2}=\left(\frac{x^2}{b}-\frac{2a^2}{b^3}\right)\frac{1}{a+bx}-\frac{2a}{b^3}\,\mathrm{hl}\,(a+bx)$$

$$15.\int\frac{x^3dx}{(a+bx)^2}=\left(\frac{x^3}{2b}-\frac{3ax^2}{2b^2}+\frac{3a^3}{b^4}\right)\frac{1}{a+bx}+$$
$$\frac{3a^2}{b^4}\,\mathrm{hl}\,(a+bx)$$

$$\text{c. }\frac{x^{M}dx}{(a+bx)^3}$$

$$16.\int\frac{dx}{(a+bx)^3}=-\frac{1}{2b(a+bx)^2}$$

$$17.\int\frac{xdx}{(a+bx)^3}=-\left(\frac{x}{b}+\frac{a}{2b^2}\right)\frac{1}{(a+bx)^2}$$

$$18.\int\frac{x^2dx}{(a+bx)^3}=\left(\frac{2ax}{b^2}+\frac{3a^2}{2b^3}\right)\frac{1}{(a+bx)^2}+\frac{1}{b^3}$$
$$\mathrm{hl}\,(a+bx)$$

$$19.\int\frac{x^3dx}{(a+bx)^3}=\left(\frac{x^3}{b}-\frac{6a^2x}{b^3}-\frac{9a^3}{2b^4}\right)\frac{1}{(a+bx)^2}$$
$$\frac{3a}{b^4}\,\mathrm{hl}\,(a+bx)$$

$$\text{d. }\frac{dx}{x^{M}(a+bx)}$$

$$20.\int\frac{dx}{x^{M}(a+bx)}=-\frac{1}{(M-1)ax^{M-1}}+$$
$$\frac{b^2}{(M-2)a^2x^{M-2}\quad(M-3)a^3x^{M-3}}+\dots$$
$$\frac{b^{M-1}}{M}\,\mathrm{hl}\,\frac{a+bx}{x}$$

Examples.

$$21.\int\frac{dx}{x(a+bx)}=-\frac{1}{a}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$22.\int\frac{dx}{x^2(a+bx)}=-\frac{1}{ax}+\frac{b}{x^2}\quad a+bx$$

$$23.\int\frac{dx}{x^3(a+bx)}=-\frac{1}{2ax^2}+\frac{b}{a^2x}-\frac{b^2}{a^3}\,\mathrm{hl}\,\frac{a+}{}$$

$$x^{M}(a+bx)^2$$

$$24.\int\frac{dx}{x(a+bx)^2}=\frac{1}{a(a+bx)}-\frac{1}{a^2}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$25.\int\frac{dx}{x^2(a+bx)^2}=\left(-\frac{1}{ax}-\frac{2b}{a^2}\right)\frac{1}{a+bx}+$$
$$\frac{2b}{a^3}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$26.\int\frac{dx}{x^3(a+bx)^2}=\left(-\frac{1}{2ax^2}+\frac{3b}{2a^2x}+\frac{3b^2}{a^3}\right)\frac{1}{a+bx}$$
$$-\frac{3b^2}{a^4}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$\text{f. }\frac{dx}{x^{M}(a+bx)^3}$$

$$27.\int\frac{dx}{x(a+bx)^3}=\left(\frac{3}{2a}+\frac{bx}{a^2}\right)\frac{1}{(a+bx)^2}\cdot$$
$$\frac{1}{a^3}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$28.\int\frac{dx}{x^2(a+bx)^3}=\left(-\frac{1}{ax}-\frac{9b}{2a^2}-\frac{3b^2x}{a^3}\right)\frac{1}{(a+bx)^2}$$
$$+\frac{3b}{a^4}\,\mathrm{hl}\,\frac{a+bx}{x}$$

$$29.\int\frac{dx}{x^3(a+bx)^3}=\left(-\frac{1}{2ax^2}+\frac{2b}{a^2x}+\frac{9b^2}{a^3}+\frac{6b^3x}{a^4}\right)$$
$$\frac{}{(a+bx)^2}-\frac{6b^2}{a^5}\,\mathrm{hl}\,\frac{a+bx}{}$$

$$\text{B. }\quad x^{m}(a+bx^2)^{-N}dx$$

$$\text{a. }\frac{x^{M}dx}{a+bx^2}$$

A. sin. $^{M}\phi d\phi$

351. $\int \sin\phi d\phi = -\cos.\ \phi$

352. $\int \sin^2\phi d\phi = -\frac{1}{2}\sin\phi\cos\phi+\frac{1}{2}\phi$
$= -\frac{1}{4}\sin 2\phi+\frac{1}{2}\phi$

353. $\int \sin^3\phi d\phi = \left(-\frac{1}{3}\sin^2\phi-\frac{2}{3}\right)\cos\phi$
$= \frac{1}{12}\cos 3\phi-\frac{3}{4}\cos\phi$

354. $\int \sin^4\phi d\phi = \left(-\frac{1}{4}\sin^3\phi-\frac{3}{8}\sin\phi\right)\cos\phi+\frac{3}{8}\phi$
$= \frac{1}{32}\sin 4\phi-\frac{1}{4}\sin 2\phi+\frac{3}{8}\phi$

355. $\int \sin^5\phi d\phi = \left(-\frac{1}{5}\sin^4\phi-\frac{4}{15}\sin^2\phi-\frac{8}{15}\right)\cos\phi$
$= -\frac{1}{80}\cos 5\phi+\frac{5}{48}\cos 3\phi-\frac{5}{8}\cos\phi$

356. $\int \sin^6\phi d\phi = \left(-\frac{1}{6}\sin^5\phi-\frac{5}{24}\sin^3\phi-\frac{5}{16}\sin\phi\right)$
$\cos\phi+\frac{5}{16}\phi$
$= -\frac{1}{192}\sin 6\phi+\frac{3}{64}\sin 4\phi-\frac{15}{64}\sin 2\phi$
$+\frac{5}{16}\phi$

B. cos $^{M}\phi d\phi$

357. $\int \cos\phi d\phi = \sin\phi$

358. $\int \cos^2\phi d\phi = \frac{1}{2}\sin\phi\cos\phi+\frac{1}{2}\phi$
$= \frac{1}{4}\sin 2\phi+\frac{1}{2}\phi$

359. $\int \cos^3\phi d\phi = \left(\frac{1}{3}\cos^2\phi+\frac{2}{3}\right)\sin\phi$
$= \frac{1}{12}\sin 3\phi+\frac{3}{4}\sin\phi$

360. $\int \cos^4\phi d\phi = \left(\frac{1}{4}\cos^3\phi+\frac{3}{8}\cos\phi\right)\sin\phi+\frac{3}{8}$
$= \frac{1}{32}\sin 4\phi+\frac{1}{4}\sin 2\phi+\frac{3}{8}\phi$

361. $\int \cos^5\phi d\phi = \left(\frac{1}{5}\cos^4\phi+\frac{4}{15}\cos^2\phi+\frac{8}{15}\right)\sin\phi$
$= \frac{1}{80}\sin 5\phi+\frac{5}{48}\sin 3\phi+\frac{5}{8}\sin\phi$

362. $\int \cos^6\phi d\phi = \left(\frac{1}{6}\cos^5\phi+\frac{5}{24}\cos\phi+\frac{5}{16}\cos\phi\right)$
$\sin\phi+\frac{5}{16}\phi$
$= \frac{1}{192}\sin^6\phi+\frac{3}{64}\sin^4\phi+\frac{15}{54}\sin^2\phi$
$+\frac{5}{16}\phi$

C. sin $^{m}\phi$ cos $^{N}\phi d\phi$

a. sin ϕ cos $^{N}\phi d\phi$

363. $\int \sin\phi\cos^{N}\phi d\phi = -\frac{1}{N+1}\cos^{N+1}\phi$

It may be remarked that $\cos^{N}\phi=\frac{1}{2^{N-1}}\left(\cos N\phi+N\cos(N-2)\phi+N\frac{N-1}{2}\cos(N-4)\phi+\dots\right]$; continuing the series through all positive angles, and putting $\frac{1}{2}$ instead of cos 0.

b. sin $^{N}\phi$ cos $\phi d\phi$

364. $\int \sin^{N}\phi\cos\phi d\phi = \frac{1}{N+1}\sin^{N+1}\phi$

We have for the powers of sin ϕ, $\sin^{N}\phi=\pm\frac{1}{2^{N-1}}\left(\cos N\phi-N\cos(N-2)\phi+N\frac{N-1}{2}\cos(N-4)\phi-\dots\right)$; + when $N=4p$, — when $N=4p+2$; and $\sin^{N}\phi=\pm\frac{1}{2^{N-1}}\left(\sin N\phi\right.$

$$-N\sin(N-2)\varphi + N\cdot\frac{N-1}{2}\sin(N-4)\varphi - \cdots\Big),$$

+ when $N = 4p + 1$, and — when $N = 4p + 3$, the last term, when it becomes cos 0, being altered to $\frac{1}{2}$.

c. $\sin^2\varphi \cos^N\varphi\, d\varphi$

365. $$\int \sin^2\varphi\cos\varphi\, d\varphi = \frac{1}{3}\sin^3\varphi$$
$$= -\frac{1}{4}\left(\frac{1}{3}\sin 3\varphi - \sin\varphi\right)$$

366. $$\int \sin^2\varphi\cos^2\varphi\, d\varphi = \frac{1}{4}\sin^3\varphi\cos\varphi - \frac{1}{8}\sin\varphi\cos\varphi + \frac{1}{8}\varphi$$
$$= -\frac{1}{8}\left(\frac{1}{4}\sin 4\varphi - \varphi\right)$$

367. $$\int \sin^2\varphi\cos^3\varphi\, d\varphi = \left(\frac{1}{5}\cos^2\varphi + \frac{2}{15}\right)\sin^3\varphi$$
$$= -\frac{1}{16}\left(\frac{1}{5}\sin 5\varphi + \frac{1}{3}\sin 3\varphi - 2\sin\varphi\right)$$

368. $$\int \sin^2\varphi\cos^4\varphi\, d\varphi = \frac{1}{6}\sin^3\varphi\cos^3\varphi + \frac{1}{2}\int \sin^2\varphi\cos^2\varphi\, d\varphi$$
$$= -\frac{1}{32}\left(\frac{1}{6}\sin 6\varphi + \frac{1}{2}\sin 4\varphi - \frac{1}{2}\sin 2\varphi - 2\varphi\right)$$

369. $$\int \sin^2\varphi\cos^5\varphi\, d\varphi = \left(\frac{1}{7}\cos^4\varphi + \frac{4}{35}\cos^2\varphi + \frac{8}{105}\right)\sin^3\varphi$$
$$= -\frac{1}{64}\left(\frac{1}{7}\sin 7\varphi + \frac{3}{5}\sin 5\varphi + \frac{1}{3}\sin 3\varphi - 5\sin\varphi\right)$$

370. $$\int \sin^2\varphi\cos^6\varphi\, d\varphi = -\frac{1}{128}\left(\frac{1}{8}\sin 8\varphi + \frac{2}{3}\sin 6\varphi + \sin 4\varphi - 2\sin 2\varphi - 5\varphi\right)$$

d. $\sin^3\varphi \cos^N\varphi\, d\varphi$

371. $$\int \sin^3\varphi\cos\varphi\, d\varphi = \frac{1}{4}\sin^4\varphi$$
$$= \frac{1}{8}\left(\frac{1}{4}\cos 4\varphi - \cos 2\varphi\right)$$

372. $$\int \sin^3\varphi\cos^2\varphi\, d\varphi = \left(\frac{1}{5}\sin^4\varphi - \frac{1}{15}\sin^2\varphi - \frac{2}{15}\right)\cos\varphi$$
$$= \frac{1}{16}\left(\frac{1}{5}\cos 5\varphi - \frac{1}{3}\cos 3\varphi - 2\cos\varphi\right)$$

373. $$\int \sin^3\varphi\cos^3\varphi\, d\varphi = \left(\frac{1}{6}\cos^2\varphi + \frac{1}{12}\right)\sin^4\varphi$$
